The interaction with illiterate people is a common experience in Egypt. More than one third of the adult population is not able to read and write (UNICEF, 2012). One could conclude that due to these every-day encounters, illiterates would be appreciated as they represent an important part of Egyptian's workforce and are preservers of Egyptian's rich cultural heritage. The Egyptian society, however, marks clearly its division not only based on economic power. Throughout the country, illiteracy is commonly associated with a lack of mental and cognitive capabilities that leads to a tremendous depreciation of this group by the literate part of the society (Hollingshead, 1975). Given the nature of this stereotype, the area of problem-solving strategies has been chosen for comparison. The motivation of the research is to explore this cultural gap and find ways to bridge it.

Several approaches to cultural differences in problem-solving have been explored in the past. Tedre et al. have shown how computation is done across different cultures and looked at the education of computer science students (Tedre, Sutinen, Kahkonen, & Kommers, 2003). Gerdes looked in a similar way at the cultural differences on math and mathematical problem solving (Gerdes, 2005). Several researches suggest that human reasoning is based on building personalized mental models; hence using mental models in attempting to formalize and represent reasoning is a valid approach (Knauff, Mulack, Kassubek, Salih, & Greenlee, 2002). In addition to formulating the models, the field of cognitive psychology also draws attention to the basic thinking principles

that are present in all individuals, but are used differently across cultures. It was used in combination with cross cultural psychology, which is the study concerned with the thinking principles that are generated from cultural differences (Adler & Gielen, 2001). This field has been used by many researches to study how education affects cognitive behaviors, memory, problem solving and logical reasoning (Segall, Dasen, Berry, & Poortinga, 1999).

Based on this previous work and the given circumstances in Egypt, it was decided to look at reasoning and algorithmic problem solving tasks together with the mental models created during the process for both literate and illiterate subjects including different educational domains.

## Problem Space

### Domain Selection

It was hypothesized that the level of a person's formal schooling is related to the level of formality regarding their approach to the selection of problem solving strategies. The functionally illiterate subjects in this context are compared to the formal schooling subjects as having a lower level of schooling formality (Kosmidis, Zafiri, & Politimou, 2011). Hence, domains that need a formal and strategic approach were selected for this research. The goal was to identify and quantify problem-solving strategies easily. Numeric problem solving, algorithmic problem solving and reasoning meet this requirement. As the relationship between literacy and numeracy has been widely studied in this context already, the two latter domains were selected.

### Algorithm Domain

The main focus while testing the algorithmic domain was to identify the subjects strategies in conjunction with the level and type of education while solving a procedural algorithmic problem. The subjects were asked for a self-report on their strategies. This report was contrasted with the steps they actually took in solving the problem. The Towers of Hanoi problem was used to test this domain due to its strong mathematical basis and the possibility to easily adapt it to different cultural contexts. This was specifically important for the illiterate subjects that are not used to any kind of formal testing situations encountered in the lab. The most important characteristic of the Towers of Hanoi consists in the variety of

correct strategies to solve it. Hence, this did not limit the subjects options to only one correct way, but would allow them to select the strategy they are most comfortable with based on their personal literacy backgrounds (Gunzelmann & Anderson, 2001). The expected problem solving strategies were: analogy, divide and conquer, mean-ends analysis, trial and error, random strategy, research and working backwards (Chiew & Wang, 2004). In addition to the problem solving strategy, the mental model created by the solver during the test was of special interest, too. It was expected that solvers would have one of the following mental models:

- Formal Representation: Using logic and formal mathematical representation for the problem.
- Previously-Prepared Mental Model: Solver solves the entire problem in their mind before solving on board.
- On-the-go Mental Model: Subjects build an image of the disks in their mind and use it to solve the problem virtually before physically, a few steps at a time.
- No Representation

A dynamic, additional element in form of a random disk was introduced by the test facilitator during the test in order to be able to distinguish between subjects that would apply a previously prepared model and subjects that would create the models on-the-go. The subject was asked to proceed with the solution using the additional disk. This procedure provided the opportunity to check, in addition, the degree of agility of the subjects strategy as well as their understanding of the problem. The point in time as well as the type of disk added was determined by the facilitator during the test based on the subject's performance.

## Reasoning Domain

Reasoning was used as a problem solving domain in this research based on the previous work of Tulviste et al. (1978). They have shown that reasoning is a skill that improves strongly with the level of literacy (Tulviste, Riikliku, & Toimetised, 1978). Several types of reasoning were considered for this study. Syllogistic deductive reasoning was selected as studies have shown that it is a skill that comes with formal schooling and evolves to be used in everyday life on different types of problems. In addition, the mental proof theory shows that syllogistic deductive reasoning is approached by solvers using one of the following techniques (Knauff et al., 2002; Rips, 1994): spatial reasoning, visual reasoning or reasoning using formal logic, entailing a variety of strategies with different levels of formality that relates to the level of the subjects formal schooling. The Zebra puzzle was suggested as a research test question (Stangroom, 2010). The approach needed to solve the problem, however, requires that the subjects use a formalized written schedule. This would have forced them to select one strategy over the others for correctness instead of their own personal preference. Moreover, it would have meant that illiterate subjects would have

never been able to solve it as they are not able to use pen and paper for their solution. Therefore, a smaller version of the puzzle with only 3 instead of 5 variables was created as stated below:

A street has 3 houses, each house has a different color, and in each house the owner has a different nationality and owns a different pet. Given these following clues, what is the color of the fish's house?

- The cat lives in the center house.
- The green house is on the left.
- The French lives in the blue house.
- The German owns a dragon.
- The Egyptian lives in the red house directly to the right of the dragon.

Subsequently, the subjects were asked to answer the following question: what is the color of the fish's house?

The spatial memory is used for solving the Towers of Hanoi Problem while deductive syllogistic reasoning tasks tend to make use the verbal memory (Handley, Capon, Copp, & Harper, 2002). Studies have shown that the performance of both types of memory is independent from each other. Measuring the performance, however, was not the main objective to measure in this study but rather the strategy selection. This selection, as mentioned before, is hypothesized to depend on the subjects formal schooling independent from the type of memories. Therefore, it is expected that the subjects show a similar selection of strategies for both domains chosen here.

## Hypothesis and Test Design

### General Hypothesis

Figure 1: Towers of Hanoi strategy selection tree

It was hypothesized that the strategy selected for the Towers of Hanoi would be based on the formality of the subject's education as shown in figure 1. In addition, it was hypothesized that the subjects may move between different strategies when solving the problem. This shift, however, would be minimal as the general tendency is expected to be clear and stable.

## Test Design

The following profiles were defined for the test subjects in order to test the hypotheses mentioned above:

- 20 computer science university students, who received training in formal logic.
- 20 Illiterate subjects, who are now in their early stages of literacy classes. The short class-room experience equipped them with the necessary preparation and tolerance towards participating in the experiments.
- 20 applied arts university students, who have only received formal schooling but no training in formal logic. They have, however, strong spatial reasoning skills.

The content of the test has been adapted to Egyptian illiterate. The deductive reasoning problem became the narration of a story replacing nationalities with common names and pets with farm animals. The Towers of Hanoi problem was contextualized by representing the disks with water buckets of different sizes and the pegs with floor tiles. The explanation of the problem was based on a story to justify the reason for moving the buckets.

During the test, the subjects' age, study-major (if applicable) and duration in literacy class (if applicable) were captured. This data defined the independent variables as follows: Level of literacy, type of education and training in formal logic. In addition, the subjects were asked questions regarding their approach, mental representations and changes in strategies. The strategy was classified as either: none, on-the-go or prepared beforehand. The following dependent variables were recorded: completion of task (y/n), time for task completion, number of attempts in deductive reasoning, approach to deductive reasoning, Towers of Hanoi strategy selection, Towers of Hanoi strategy change, Towers of Hanoi adaptation to dynamic disk addition.

## Subject-Specific Hypothesis

Figure 2 and tables 1 and 2 represent the three hypotheses of each subject background.

Figure 2: Towers of Hanoi Hypothesis

## Test Results and Discussions

### Pretest

A pretest was conducted using the above test design on engineering students who have studied the Constraint Program-

Subject	Mental Representation
Computer Science	Numerical and Formal
Applied Arts	Visual model
Illiterates	Visual model or none

Table 1: Towers of Hanoi Mental Model Hypothesis

Subject	Approach	Memory
Computer Science	Formal Logic	Verbal Memory
Applied Arts	Spatial Reasoning	Spatial Memory
Illiterates	Intuition	N/A

Table 2: Deductive Reasoning Hypothesis

ming course, applied arts students and Illiterate subjects. No modifications were recommended for applied arts and illiterate tests. . All of the engineering students, however, were already familiar with the solution to the Towers of Hanoi problem. Therefore, another control group with a lower level of formal training was added. This new group consisted of computer science students in their sophomore year. The results recorded for the deductive reasoning question were observed by asking the subject questions about their strategy and deducing their approach from the paper they used in solving. After the test, it was concluded that there is no observed difference when using spatial or visual reasoning and that both strategies may have different mental representations, but they use the same inference technique.

## The Main Test Results

The Towers of Hanoi problem was analyzed in two steps: the observation and the inference. The observed results are the strategies recognized by the facilitator. They were recorded because it was difficult for some of the subjects to properly explain their own approach. They included:

- The Random strategy was recorded when the subject showed no learning pattern and moved the disks haphazardly often reaching no correct solution.
- The Trial and Error strategy was recorded when the subject first started moving disks randomly and then appeared to recognize incorrect moves and avoided repeated them, this was often observed when the board reaches a similar state to a previously encountered stage and the subject seemed to recall their previous error.
- The Wrong Towers strategy was recorded when the subject used the right pattern of movements but choose the wrong destination for the movement of the first disk.
- The Correct strategy was recorded when the subject used the right pattern of movements from the first move without any errors.

The inferred results were reported by the subjects' own explanation of their strategy. They were used in addition to the observed strategies for the final analysis and included:

- Random strategy was recorded when the subject says that they did not understand the game and they just moved the disks in any fashion attempting to reach a solution.
- Trial and Error strategy was recorded when the subject says that at first they started without knowing how to proceed, but with time they understood the game and learned from their errors.
- Pattern Recognition occurs when the subject identifies patterns. A pattern is a group of disks stacked in a certain way on the board. The pattern recognized by subjects were either the 3-disk pattern, disks stacked on top of each other or the flat pattern. The flat pattern means that three disks are placed on the board, while each disk is placed on a different tower. The subjects would always follow a learned set of moves upon identifying any of the patterns.
- Mean Ends Analysis was recorded when the subject says they solved the problem by breaking it down and attempting to move the largest disk to the destination first, which required moving all the disk stacks above it to the intermediate tower and so forth. This strategy was recorded when the subjects identified the recursive nature of the problem.

The following are the observed and inferred results for each group of test subjects:

- Computer science students trained in constraint programming were almost equally divided between using the formal approach (12) and spatial reasoning (8) for the deductive reasoning problem as opposed to the original hypothesis of a high tendency for formal approach. Those who choose a formal approach tended to use mean-ends analysis to solve the Towers of Hanoi before and after adding the dynamic disk. The ones that used spatial reasoning were divided between trial and error and mean-ends analysis before adding the disk and continued to use their selected strategy after addition of the disk.
- Engineering subjects tended to choose spatial reasoning (17) over formal approach (3) for solving the deductive reasoning problem, as opposed to the hypothesis that they would have a tendency for a formalized approach. For the Towers of Hanoi, most of them used mean-ends analysis before disk addition. Only a few used pattern recognition, too. The majority that used mean-ends continued after the disk addition with mean-ends, whilst only a few applied Trial and Error. Those who selected pattern recognition were equally divided upon the four strategies after disk addition.
- Applied Arts subjects mostly selected spatial reasoning (18) as hypothesized. A surprising 10%, however, approached the deductive reasoning problem with a formal strategy (2). The applied arts subjects were the most diversified in their strategy selection showing that their education did not seem to limit their approach. They were

equally divided upon all strategies before and after disk addition except for the unselected random strategy.

- As hypothesized, 100% of the illiterate subjects (20) used spatial reasoning to solve the deductive reasoning problem. The subjects were evenly divided between all the four strategies of the Towers of Hanoi before disk addition. This contradicted the initial belief that all illiterates would approach the problem in a random way. Upon dynamic disk addition, most of the subjects would either continue using their current strategy or use a strategy that is one degree less formal according to the hierarchy shown in figure 3. The results clearly indicate that illiterates were affected by the disk addition process.

### Statistical Results Analysis

The different strategies were numbered according to the pyramid shown in figure 3. In order to determine the significance of the results, the Kruskal Wallis test was used.

Subject	N	Min	Max	Median
Constraint Programming	20	4.0	2.0	4.0
Arts	20	2.0	4.0	2.0
Engineering	20	3.0	4.0	4.0
Illiterates	20	1.0	4.0	2.0

\*p < .01

Table 3: The statistical analysis of all groups before addition

H=12.65\*

Subject	N	Min	Max	Median
Constraint Programming	20	4.0	2.0	4.0
Arts	20	2.0	4.0	2.0
Engineering	20	2.0	4.0	4.0
Illiterates	20	2.0	4.0	2.0

\*p < .01

Table 4: The statistical analysis of all groups after addition

H=12.30\*

Both tests were statistically significant at a 1% level of significance. Therefore, we can state that the literacy and formal schooling background significantly affects the selection of problem-solving strategies when solving the Towers of Hanoi problem. In addition and in line with the initial assumption, there was no correlation found between the task performance and the level of formality of the selected strategy ( $p = .08$ ). This means that the use of formal methods did not lead to a faster performance in comparison to using spatial reasoning. Finally, the effect of literacy on the type of mental model created in the Towers of Hanoi problem was tested. The results showed no statistical significance ( $p = .94$ ). This shows that all four subject domains created spatial, beforehand or no mental models depending on a different parameter other than their

educational backgrounds. It also showed that strategy selection in the Towers of Hanoi problem is not entirely dependent on the mental model created as opposed to the original hypothesis, since the selection of the strategy proved to be dependent on the subject's educational background.

The original hypothesis of the tree of problem selection strategies was not confirmed. It was rather observed that the strategy selection was done using the pyramid shown in figure 3. The strategies are ranked according their proximity to the most optimum Towers of Hanoi algorithm with one being the least optimum. It was observed that subjects would start at a level of the above pyramid depending on their level and type of formal education, their working background and their understanding of the problem and rules. Subjects go up the pyramid but never down. No subject was observed to move 2 levels up the pyramid, they only move up 1 level per game or none at all. Once an additional disk was introduced, however, most subjects would move down the pyramid considering the new situation a new problem. Some of the subjects did not even capitalize on the previous knowledge they obtained before the addition of the new disk.

Figure 3: Towers of Hanoi Observations

## Software Model

As a first step towards possible future prediction of cognitive behaviors of subject profiles, a software model was used to represent the strategies observed. It was implemented to formalize and represent the test results and experiment with new strategies. It was also implemented as a guidance for predicting problem solving strategy selection and execution based on a given subject profile. Having such a tool can help educational institutes in understanding the mindset of their target groups as well as guide them through their cognitive development needs which will assist in curricula formation. Four agents were created, one for each subject background and the agents navigated between the strategies implemented below according to the percentage of subjects within that background recorded to use that strategy. The model was created on Java as its object-oriented nature facilitated the implementation and its high-level characteristic allowed enough abstraction to represent only the details examined during the tests.

## Modeling Reasoning

The reasoning problem strategies were modeled separately for formal representation and spatial reasoning.

Formal reasoning was modeled using Constraint Programming. Constraint Programming (CP) is a recent paradigm based on artificial intelligence and declarative programming (Rossi, Beek, & Walsh, 2006). Its advantage over other programming methodologies is its abstraction. The houses are represented as a data domain from 1 to 3 and the pets, nationalities and colors as sets of variables that associate with these domains. By placing the puzzle restrictions above on the representation, the CP solver finds the house that has no pet and allocates the fish to it.

The spatial reasoning model was simulated the way the solvers described their approach. A list of possible streets was kept in the subject's brain at a time. Each street had its unique configuration of houses. Upon presenting the subject with an additional clue from the puzzle, the subject attempts to add this to his current streets list. A clue can either be added to an existing street, if it can be merged with one, delete an existing street, if it presents a contradiction showing the initial street was not correct, or create a new street, if that clue cannot be represented sufficiently within the existing context. At the end of the puzzle, the subjects have eliminated all incorrect streets and are left with one street.

## Modeling Towers of Hanoi

The following four strategies are modeled separately:

- **Random Strategy:** Each move entails moving a randomly selected disk to a random tower.
- **Trial and Error:** The trial and error strategy implementation was divided into two modules: representing memory and using learning, and representing how the subject learned from their movements. Only the first module was implemented and the second was left as future work. The approach represented the subject's memory as a pre-set number of movements that they have executed. The memory starts as initially empty. Before undergoing any movement, the agent checks if the current game uses a configuration that the subject has already learnt, in this case it switches to the pattern identification strategy below. If the game represents a pattern that the subject did not learn yet, it marks the current move. The subject selects a disk using a random generator in this case. After the second module mentioned above will be implemented, however, it will be constricted by learning. Once a move is executed, it is saved into the subject's memory. If there is no space in the memory, the oldest move is deleted. Now, the agent checks upon the last sequence of moves starting from the marked one. If they have solved the pattern correctly up to the pattern threshold, then the subject learned the pattern. A pattern threshold is the initial number of difficult moves the subject needs to do to understand a pattern. The rest of the moves then come easily as described and observed during tests.

- Pattern Identification: The 3-pattern and flat pattern as described in Test Results and Discussions section are implemented. The first disk destination is selected randomly.
- Mean-Ends Analysis: The algorithm moves all disks smaller than the  $n$ th disk to the intermediate tower. The  $n$ th disk is then moved to the destination tower. Finally, all the disks at the intermediate tower are moved on top of the  $n$ th disk at the destination using the same fashion.

## Conclusion

This research has tested the hypothesis that *cognitive ability improves with literacy* is a common misconception. It is rather the case that the selection of given strategies is affected by the literacy background.. The hypothesis was proven correct in both the domain of reasoning and algorithmic problems. The relationship between these two domains was also examined in this research. It was hypothesized that individuals who select a formal problem solving strategy in one of them would select a formal one in the other. This formality would be directly traced back to their level of formal schooling. The hypothesis was confirmed. It was shown that, despite the fact that deductive reasoning is located in a different part of the working memory than algorithmic problem solving and that both cognitive processes are completely independent, the level of formal schooling equally impacts both.

A software model was based on the findings of the research and represented agents from the following literacy backgrounds: Illiterates, Computer Science, Constraint Programming and Applied Arts students. The agents used the different cognitive approaches of each subject domain to solve the Towers of Hanoi problem and a deductive syllogistic reasoning problem adapted from the Zebra puzzle.

## Future Work

The software model can be enhanced by adding the second element of the Trial and Error learning system using reinforcement learning technique. It may also be broadened after adapting more tests to present a general thinking pattern in the domains of algorithmic problem solving and reasoning by the agents. This would mean that the model, given any newly introduced problem within these two domains, would be able to simulate the behavior of a given subject's profile. Finally, the model may be built on a pre-existing cognitive framework which will improve its accuracy and make it more representative of the human brain.

This model can be used to enhance the understanding of the different cognitive profiles in the Egyptian society. It can be used by Education Scientists to understand the cognitive gap generated by the literacy cultural gap and make use of the country's "cultural capital" as referred to by Pierre Bourdieu (Bourdieu, 1984). This capitalization can best be practiced by analyzing the reason behind these cognitive gaps and adapting the school, university as well as literacy classes curricula to make use of this information. In addition, the newly improved model can be used to test how students would think

and adapt to different problems presented to them to predict their understanding and cognitive behavior.

# Shared Book Reading between Mother and Infant Facilitates The Frequency of Joint Attention

Ayumi Sato (ayusatotenjin@gmail.com)

Department of Psychology, Graduate School of Letters  
Doshisha University, Japan

Faculty of Psychology, Doshisha University, Japan

## Abstract

This study examines the effect of shared book reading on mother-infant joint attention interactions in infancy. In experiment 1, pairs composed of 9-month-old infants and their mothers ( $N = 10$ ) were observed in three conditions: the shared-book, toy-play, and no-material condition. The results indicate a frequency of passive joint and coordinated joint attention in the shared book context than in others. Experiment 2 longitudinally investigated the effect of increasing the time of shared book reading on the frequency of passive and coordinated joint attention. Twenty-eight pairs of 9-month-old infants and their mothers were randomly assigned to one of two groups; the first was a shared book reading condition ( $N = 11$ ), in which mothers were asked to share books every day and were given picture books regularly from the first observation (at 9 months) until the second observation (at 12 months). In the control group ( $N = 11$ ), mothers were given no instruction. The results show that increasing shared book reading increases the frequency of passive joint attention. Therefore, it is suggested that shared book reading increases joint attention episodes and that repeated shared book reading increases it in other contexts.

**Keywords:** shared book reading; joint attention; mother-infant interaction; infancy; longitudinal study

## Introduction

Shared book reading at home has been advocated as a method of enhancing children's language abilities. In 1992, Bookstart was started by Booktrust in Birmingham, U.K. This program distributes picture books and booklets for shared book reading to infants and their mothers. One of its goals is promoting pre-school child literacy; thus, follow-up surveys on literacy changes in children whose mothers received Bookstart packs were conducted to evaluate the project. For example, the timing of start of the shared book reading was reported as the strongest predictor variable in the literacy of two-year-olds (DeBaryshe, 1993). It was suggested that the earlier mothers and children started sharing picture books, the better the children were at comprehension and speaking (Payne, Whitehurst, & Angell, 1994). Wade & Moore (1998) reported that children whose mothers received Bookstart packs were better at not only reading and writing skills but also mathematics than were children whose mothers had not. Many studies agree that shared book reading promotes children's language skills.

The mechanism of shared book reading's enhancements has not been clear, but one factor is thought to be joint

attention. Tomasello (1995) argues that joint attention is characterized by the coordination of attention among the self, the other, and some external object or event. Shared book reading is thought to be an exceptional opportunity for the occurrence of joint attention (e.g., Karrass, VanDeventer, & Braungard-Rieker, 2003). It is known that joint attention plays an important role in children's language acquisition (e.g., Tomasello & Farrar, 1986). Repeated joint attention between mothers and infants makes mother-infant interactions predictable for infants and renders mapping words on the world easier (Bruner, 1985). As shared book reading provides more episodes of joint attention, it is thought to promote child literacy.

However, whether joint attention episodes occur more often during shared book reading than in other contexts has not been clear. Although many studies have used the shared book context to observe joint attention (e.g., Fletcher, Perez, Hooper, & Claussen, 2005) and have used both picture books and toys at once (e.g., Bakeman & Adamson, 1984; Mundy & Gomes, 1998), few studies have discussed shared book reading separately or compared its joint attention effects with those in other contexts (e.g., toy play).

The few extant studies involve infants older than one year. For example, Yont, Snow, & Vernon-Feagans (2003) compared mothers' utterances to their 12-month-old infants during shared book events with those during toy play and found that the number of utterances about objects made during the mothers' shared attention with their infants was higher in the shared book context than in the toy play one. Another study found that mothers and their 18-month-olds pointed more often in the shared book context than in the wooden block play one (Sugai, Akita, Yokoyama, & Nozawa, 2010). Therefore, shared book reading increased mother-infant joint attention interactions when the infants were older than 12 months.

However, whether shared book reading promotes the number of joint attention episodes in infancy hasn't been confirmed. It is in infancy, especially at around 9 months, that a child's joint attention capacity develops most rapidly (Dunham & Moore, 1995). It is thus necessary that the frequency of joint attention in infancy be compared to shared book reading and other play contexts. Furthermore, an important question is whether continued shared book reading changes the joint attention in mother-infant interaction. If shared book reading facilitated children's

joint attention abilities, joint attention frequency would increase in the other contexts (e.g., a toy-play context) through repeated shared book reading. To investigate this possibility, we need to increase the shared book reading time and examine its effect on joint attention frequency in the other contexts.

Therefore, this study investigates the effect of shared book reading on joint attention frequency by comparing shared book reading and other contexts in experiment 1. Next, we intervene in the shared-book condition group by increasing its shared book reading time; then, we longitudinally compare its joint attention frequency in a toy play situation with that of the control group.

## Experiment 1

To investigate whether shared book reading increases joint attention episodes more than other play contexts, we compared the number of joint attention episodes during the shared book reading, toy play, and no material contexts, all common for 9-month-old infants and their mothers. To measure mother-infant joint attention frequency in these free play situations, we used indexes defined by Bakeman & Adamson (1984). Bakeman & Adamson (1984) performed longitudinal observations and indexed descriptions of the joint attention of infants from 6 to 18 months and their mothers in free play situations at home (using picture books and toys) and found that mothers' behavior is important for the occurrence of joint attention in infancy. Bakeman & Adamson (1984) divided joint attention episodes into two components; passive joint and coordinated joint. Passive joint occurs when mothers actively draw the infants' attention to an object, and coordinated joint occurs when infants voluntarily become involved in play and coordinate their attention to both mothers and objects. In passive joint, mothers need actively to lead the infants' attention; once coordinated joint begins, the mother must follow the infant's attention. Bakeman & Adamson (1984) suggest that mothers' coordinated behavior promotes children's joint attention development.

As Yont et al. (2003) and Sugai et al. (2010) show, mothers seem to draw their infants' attention to an object more frequently in the shared book context than in other contexts, and passive joint appears to occur in that context more frequently than in others. On the other hand, coordinated joint behavior may decrease in the shared book context because it does not need mothers' active behavior but rather coordinated and relatively passive behavior.

## Method

**Participants** Ten 9-month-old infants and their mothers participated in this study. The mothers were recruited from an official health center when bringing their children in for checkup.

**Procedure** Each mother and infant pair individually visited a university laboratory. First, they played freely in a play room for a few minutes and were told that we would videotape their interactions. When they seemed to relax and

play actively, they moved into the next room for the recording sessions.

**Conditions** All mothers and infants participated in three conditions: (a) in the shared-book condition, the infant and mother were observed while playing on the floor with a set of picture books we provided. We used the word "play" rather than "read" when we instructed them to prevent mothers from feeling they had to read the materials consecutively; (b) in the toy-play condition, the infant and mother played with a set of toys we provided; (c) in the no-material condition, the infant and mother played without using any materials.

Before each session, the mother was instructed to play freely, as if at home. After the instructions, an experimenter moved into a curtained area and sat calmly out of sight of the pair.

Each condition session lasted for about ten minutes and was conducted on different days. The second condition session wasn't conducted until at least three days after the first one, and the third didn't begin until at least three days after the second. The order of the conditions was counterbalanced.

**Materials** In two conditions, the mother and child used the materials we provided: (a) in each shared-book condition session, a set of picture books was used, consisting of ten books (*Harapeko-Aomushi* [*The Very Hungry Caterpillar*], *Jya-Jya Biri-Biri*, *Kingyo-ga Nigeta*, *Otsukisama-Konbanha*, *Kutsu-Kutsu-Aruke*, *Gatan-Goton Gatan-Goton*, *Nenai-ko Dareda*, *Wanwan-Nakunoha-Dare*, *Kuttuita*), all in Japanese. They were ranked in the top 10, by a bookstore near the university when surveyed on the bestselling picture books for 9-month-olds; (b) in each toy-play condition session, a set of ten toys was used: a ball containing a bell and a small doll, a handkerchief that makes paper sounds, a rattle, a toy telephone, a cloth bar that makes a funny sound, a toy trumpet, a roly-poly, a pacifier, a toy car containing a bell, and a toy tambourine. These had also been ranked in the top 10 by a toy store near the university when surveyed on the bestselling toys for 9-month-olds.

**Coding** After the above sessions, the videotaped mother-infant interaction was coded for ten minutes by an experimenter sitting out of sight of the pair. Six categories of engagement, as defined by Bakeman & Adamson (1984), were used to code the interactions: (a) unengagement, in which the infant appears uninvolved with the mother, object, or activity, although he or she might be scanning the environment; (b) onlooking, in which the infant is observing the mother's activity, often quite intently, but not taking part in the activity; (c) persons, in which the infant is engaged with just the mother (typically involving face-to-face or individual play, as, for example, when infants giggle and coo when their mothers place their face close to theirs and tickle them); (d) objects, in which the infant is involved in playing with objects alone, attending only to the books, toys, or whatever is at hand; (e) passive joint, in which the infant and mother are actively involved in the same object but the infant evidences little awareness of the mother's

involvement or even presence (mothers often attempt to induce this state by manipulating objects in ways that seem designed to capture their infants' attention and make the objects "come alive" for them); and (f) coordinated joint, in which the infant is actively involved in and coordinates his or her attention to both mother and the object the mother is involved with (as, for example, when the infant pushes a toy car the mother has been pushing and then looks back and forth between the mother's face and the toy car). If the infant gazes the object only by mother's attention drawing behavior and gazes mother's face only by mother's voice but doesn't keep gazing just one of them and doesn't voluntarily shift attention between them, the episode was coded into passive joint. On the other hand, if the infant alternately shift attention between them on his or her own initiative, the episode was coded into coordinated joint.

Fifty percent of the sessions were coded independently by two experimenters. The degree of agreement was gauged using Pearson's product-moment correlation coefficient ( $r$ ). The  $r$ s ranged from .91 to .98.

## Results

The average durations of the six engagements (unengagement, onlooking, persons, objects, passive joint, and coordinated joint) during each condition (shared-book, toy-play, and no-material) are presented in Table 1. These durations were analyzed with the conditions using a repeated-measures analysis of variance (ANOVA), run separately for each engagement category. The results of ANOVA indicated significant differences in unengagement, persons, objects, passive joint, and coordinated joint ( $F(2,18) = 22.76, p < .01, \eta_p^2 = .72$ ;  $F(2,18) = 53.07, p < .01, \eta_p^2 = .92$ ;  $F(2,18) = 20.47, p < .01, \eta_p^2 = .69$ ;  $F(2,18) = 29.04, p < .01, \eta_p^2 = .76$ ;  $F(2,18) = 13.02, p < .01, \eta_p^2 = .59$ , respectively) and no significant difference in onlooking. Multiple comparison tests (Bonferroni,  $p < .05$ ) were conducted in the former five categories.

In unengagement and persons, the mean duration in the no-material condition was significantly longer than in the shared-book and toy-play conditions. There was no significant difference between the shared-book and toy-play conditions. In objects, the mean duration in the shared-book condition was significantly longer than in the no-material

and that in the toy-play was significantly longer than in the shared-book. In passive joint and coordinated joint, the mean duration in the toy-play condition was significantly longer than in the no-material, and that in the shared-book was significantly longer than in the toy-play.

## Discussion

Passive joint occurred more often in the shared book context than in other contexts, as we had predicted. These results indicate that mothers' efforts to draw infants' attention to an object seem stronger in the shared book context than in other contexts. Therefore, not only infants older than 12 months but also younger infants follow the passive joint pattern with their mothers more often in the shared book context.

One reason for this is that shared book reading requires adults. Picture books consistent with the codes (like pictures and letters) require adults to scaffold the children's understanding, as they can't read letters (Karpov, 2005). Therefore, mothers spontaneously increase active drawing attention behavior more in shared book reading context.

On the other hand, coordinated joint also increased more in the shared book reading context than in other contexts. This result shows that although the mothers actively draw their child's attention, once the coordinated joint event begins through the infant in the shared-book reading context, the mother follows the infant's attention, which coordinates their behavior and attention.

One of the reasons for this is the difference in attractiveness between picture books and toys. Many of the toys used in this study were common among 9-month-old infants and made sounds. Nine-month-olds prefer objects that make sounds and toys are more attractive than picture books. The duration results in the object category show that duration was significantly longer in the toy-play than in the shared-book context. It is known that mothers are appeased more readily when their children maintain their focus on an object (Harman, Rothbart, & Posner, 1997). When faced with unattractive objects, infants are put into bad moods, and mothers must then struggle to produce a good mood. Therefore, mothers may become sensitive about their child's attention or intent.

Table 1: The durations of the engagement states in the shared-book, toy-play, and no-material contexts.

State of engagement	Shared-Book Context		Toy-Play Context		No-Material Context	
	<i>M</i>	<i>SD</i>	<i>M</i>	<i>SD</i>	<i>M</i>	<i>SD</i>
Unengaged	141.15	63.19	84.30	19.35	292.00	111.80
Onlooking	53.90	53.92	50.30	52.85	13.35	15.61
Persons	30.30	25.72	14.40	10.12	226.90	122.84
Objects	168.85	83.40	341.60	59.38	45.45	47.81
Passive Joint	182.35	83.38	98.75	70.68	18.30	29.77
Coordinated Joint	23.60	22.23	10.95	18.91	4.00	10.36

Note: the numerical values are presented in seconds.  $N = 10$ .

## Experiment 2

In experiment 1, passive joint and coordinated joint increase more in the shared book reading context than in other contexts. As previously indicated, if shared book reading facilitates child literacy by enhancing joint attention ability, increasing the shared book reading time may promote joint attention frequency not only in the shared book reading context but also in the others. To explore this possibility, we investigated the effect of increased shared book reading time on joint attention frequency by creating a shared-book condition group and the control condition group.

A child's joint attention ability develops rapidly at around 9 months of age (Dunham & Moore, 1995). Visual joint attention (Butterworth, 1991), the act of following the direction of another's gaze (like passive joint) develops quickly between 10 and 12 months (Corkum & Moore, 1995). Moreover, active joint attention, drawing someone's attention to an object (like coordinated joint) develops at around 12 months, later than passive joint (Lempers, 1979; Leung & Rheingold, 1981). Therefore, timing our intervention (i.e., increasing the shared book reading) at between 9 and 12 months seems appropriate.

As Bakeman & Adamson (1984) suggest, coordinating the mother's behavior to her infant's is important in producing and developing the child's joint attention ability. Experiment 1 revealed how, in the shared book context, passive and coordinated joint occurred more often than in the other contexts, and the mothers' coordinate behavior occurred more frequently. Therefore, conducting shared book reading seems to facilitate the frequency of both passive and coordinated joint.

## Method

**Participants** Twenty-two 9-month-old infants and their mothers participated in this study. Recruiting occurred as in experiment 1. They were divided into two condition groups of 11 pairs each, based on the infant's age, in the first of two recorded free play sessions (for children of 9 and 12 months). One of the groups (with 6 boys and 5 girls) was the shared-book condition. The other (with 7 boys and 4 girls) was the control condition.

**Conditions** (a) In the shared-book condition, after the first recorded free play session for the 9-month-olds, each mother was instructed to share picture books with her infant at least once a day (unless something prevented it) and to visit the laboratory again when the infant was 12 months of age. The experimenter sent each mother two picture books every four weeks when the infant was between 9 and 12 months of age. The mothers received six picture books in total, chosen by her from the eight books we provided after the first recorded free play session. The aim was to motivate the mother to share books with her infant; thus sending books the mothers had already used was avoided. The eight books we provided were suggested by Bookstart Japan (2006): *Jya-Jya Biri-Biri*, *Otsukisama-Konbanha*, *Kingyoga Nigeta*, *Kudamono*, *Tamago-no-Akachan*, *Pyo-nn*, *Shirokumachan-no-Hotcake*, *Rhythm*. (b) In the control

condition, the mother was given no instructions beyond being asked to visit the laboratory again when the infant was 12 months.

**Procedure** Each mother and infant pair visited a university laboratory. First, they played freely in a play room for a few minutes and were told that we would be videotaping their interactions. When they seemed to relax and play actively, they moved into the next room for the recording sessions. After the sessions, the mother was asked to fill out a questionnaire asking her the amount of time she had spent sharing books and toys respectively with her infant in the week prior to coming for the session for both the first and second laboratory visits.

**The recorded free play session** All mothers and infants participated in the session when the infants were 9 and 12 months. They were observed while they played on the floor with a set of toys we provided. The set of toys comprised a plastic boat, a stuffed monkey, a puzzle, a set of wooden blocks, a set of shape sorting cubes, and a drawing board, as was used by Stipek, Recchia, & McClintic (1992).

Before beginning the session, the mother was instructed to play freely, as at home. After the instructions, the experimenter moved into a curtained area and sat calmly out of sight of the pair. The session lasted for about ten minutes.

**Coding** After the above sessions, the videotaped mother-infant interaction in the recorded free play session was blindly coded for just ten minutes by the experimenter sitting out of sight of the pair. In experiment 2, two of the six categories (Bakeman & Adamson, 1984), passive joint and coordinated joint, were used to code the mother-infant interactions.

Twenty-five percent of the sessions were coded independently by two experimenters. The degree of agreement was gauged with Pearson's product-moment correlation coefficient ( $r$ ). The  $r$ s of passive joint and coordinated joint were .81 and .87, respectively.

## Results

**1 Analysis of the time spent on shared book reading and interaction between mother and infant** Three data sets were missed because the mothers had no time to fill out the questionnaire after the free play session. The average amount of time spent in shared book reading and interaction between mothers and infants in each group with infants of 9 and 12 months is shown in Table 2. The time of interaction means the total time during which mother shared books or toys with her infant. Data on the mean amount of time were analyzed in a 2 (age: 9 and 12 months of age)  $\times$  2 (group: the shared-book and the control group) mixed analysis of variance (ANOVA), in which age was a within-subject and group a between-subject variable, after a logarithmic transformation. In shared book reading time, the result of ANOVA yielded a significant age  $\times$  group interaction ( $F(1, 17) = 5.79, p < .05, \eta_p^2 = .25$ ). The results of subordinate tests indicated a significant simple main effect of age in the shared-book condition group ( $F(1, 34) = 5.30, p < .05$ ), meaning that mothers shared books with their infants more

often when their infants were 12 months of age than when they were 9 months, and a significant simple main effect of group when infants were 12 months of age ( $F(1,17) = 5.02, p < .05$ ), meaning that mothers in the shared-book condition shared books with their infants when they were 12 months of age more often than in the control condition.

In interaction time, the result of ANOVA revealed no significant difference anywhere.

Table 2: The Amount of Time of Shared Book Reading and Interaction in The Shared-Book and Control Groups.

Group	9 months of age		12 months of age	
	<i>M</i>	<i>SD</i>	<i>M</i>	<i>SD</i>
Shared-Book ( <i>N</i> = 11)				
Shared book reading	60.32	100.02	97.82	73.77
Interaction	1312.14	1005.88	1141.00	769.66
Control ( <i>N</i> = 8)				
Shared book reading	60.63	68.94	35.00	35.04
Interaction	1976.88	1013.97	1302.50	501.02

Note. There numerical values are presented in minutes per a week

**2 Analysis of the number of times of joint attention episode** The average number of times of passive joint and coordinated joint in each group when infants were 9 and 12 months of age are presented in Figure 1 and Figure 2, respectively. The mean numbers of times data were analyzed in a 2 (age: 9 and 12 months of age)  $\times$  2 (group: the shared-book and the control group) mixed analysis of variance (ANOVA) where age was within-subject and group was between-subject variables.

Figure 1 The Frequency of Passive Joint in Both Groups.

In passive joint, the results of ANOVA indicated a significant age  $\times$  group interaction ( $F(1, 20) = 4.59, p < .05, \eta_p^2 = .19$ ). The results of the subordinate tests indicated a significant simple main effect of age in the shared-book condition group ( $F(1, 20) = 8.37, p < .01$ ), meaning that, in that group, the frequency of passive joint was higher when

the infants were 12 months than when they were 9 months, and a significant simple main effect of group when infants were 12 months ( $F(1, 40) = 5.67, p < .05$ ), meaning that the frequency in the shared-book condition was higher than in the control condition when infants were 12 months. The results of ANOVA also yielded a significant main effect of age ( $F(1, 20) = 3.80, p < .10, \eta_p^2 = .16$ ), meaning that the frequency of passive joint significantly increased from when infants were 9 months to when they were 12 months.

In coordinated joint, the results of ANOVA indicated a significant main effect of age ( $F(1, 20) = 13.56, p < .01, \eta_p^2 = .40$ ), meaning that the coordinated joint frequency significantly increased from when infants were 9 months to when they were 12 months.

Figure 2 The Frequency of Coordinated Joint in Both Groups.

## Discussion

The results in Table 2 show that, in the shared-book group, the amount of time spent in shared book reading significantly increased and that this time was greater for the 12-month-olds in the shared-book group than in the control group. The results in Table 2 also show that the amount of time of whole interaction was no different between groups. Therefore, our intervention through increasing the shared book reading time seems to have been successful, but it doesn't mean just increased interaction time.

As Figure 1 indicates, passive joint frequency significantly increased in the shared-book group for the 12-month-olds, and the shared-book group's frequency was higher than the control group's. Therefore, it was suggested that increasing the shared-book reading time increases the passive joint dimension.

One reason for this is that the child's joint attention ability was promoted by the shared book reading. The occurrence of passive joint allows the child to find and follow his or her mother's gaze. As indicated in Experiment 1, passive joint occurred more often in the shared book context than in other contexts. The children in shared book reading group had more opportunities to have passive joint experience and to be aware of the existence of his or her mother's gaze or attention than those in control group, which is foundation of the ability of joint attention. A child's ability to follow the direction of people's gazes (as in passive joint) develops

rapidly from 10 to 12 months (Corkum & Moore, 1995). The children in shared book reading group were promoted to be aware the existence of others' attention through their shared book reading activities at home, and it promoted the development of passive joint and the success of passive joint was higher at 12 months old.

The results in Figure 2 show that the pairs in both groups increased in coordinated joint but that there was no difference between groups. The reason involves the maturation factor in a child's coordinated joint attention ability. As mentioned, passive joint attention ability develops remarkably between 10 and 12 months (Corkum & Moore, 1995), but coordinated joint attention ability develops at around 12 months (Lempers, 1979; Leung & Rheingold, 1981). Therefore, infants in both groups developed their abilities dramatically before reaching 12 months, and the study masked the effect of shared book reading on coordinated joint. In future, we must measure coordinated joint at younger and older ages than 12 months to eliminate the influence of the maturation factor.

## Conclusion

The results of experiment 1 show that, in the shared book context, passive and coordinated joint occurred more often than in the other contexts. This indicates that, in that context, mothers actively draw their child's attention to objects but coordinately follow their child's gaze and behavior. The results of experiment 2 suggest that repeated shared book reading increased the frequency of passive joint attention not in the shared book context but in the other context. This indicates that the shared book reading experiment facilitated the child's joint attention ability and/or promoted the mother's skill at drawing the child's attention.

# A Computational PDP Model for Explaining Automatic Imitation

Matthias Scheutz (mscheutz@cs.tufts.edu)

Department of Computer Science, 165 College Avenue

Bloomington, IN 47405 USA

## Abstract

Recent evidence suggests that automatic imitation is mediated by an observation-execution matching system that cannot be reduced to the same processes responsible for other stimulus-response (S-R) compatibilities. A computational model is developed with different patterns of connectivity for imitative and spatial compatibilities, and it is successful in simulating the results from three different S-R tasks. Variations of the model with identical connections for mediating the two compatibilities reveal a significantly poorer fit. These results provide converging evidence that imitative and spatial compatibilities are mediated by different processes.

**Keywords:** automatic imitation, S-R compatibility, connectionist modeling, direct matching hypothesis

## Introduction and Background

The tendency to unintentionally and unconsciously mimic actions performed by others has long been noted. Charles Darwin, for example, commented that at leaping matches spectators would move their own feet as if imitating the athletes. More recently, Dijksterhuis and Bargh (2001) noted that we tend to whisper or speak louder when others do, scratch our heads upon seeing someone else scratch, or cycle faster after seeing a cycling race on TV. During social interactions, mimicry translates into a greater desire to want to cooperate and affiliate with those individuals imitating our gestures (Chartrand and Bargh, 1999). In spite of the frequency and significance of these behaviors, our understanding of the underlying mechanisms responsible for these automatic tendencies remains incomplete at best.

The prevailing hypothesis for explaining spontaneous mimicry or automatic imitation is that the perception of some actions automatically activates corresponding motor programs. There are by now more than 75 experimental studies investigating automatic imitation, and most of the evidence is based on stimulus response compatibility paradigms, in which both stimuli and responses involve human movements (Heyes, 2011). In this paradigm, faster responding is observed when stimuli and responses correspond along some perceptual, structural or conceptual dimension than when they do not (referred to as a “compatibility effect”). When both the stimuli and responses involve human movements, it is often assumed that automatic imitation is involved. One problem with this interpretation is that the pattern of results for automatic imitation and all other S-R compatibility effects is exactly the same (i.e., faster response times for compatible than

incompatible responses to the stimuli). As a consequence, these results beg the question as to whether the processes mediating automatic imitation are specialized or instead are the same processes involved in other S-R compatibility tasks. In order to resolve this issue, it is necessary to find a paradigm where the results for automatic imitation and other S-R compatibility tasks are predicted to be different.

We recently provided such evidence by comparing imitative and spatial compatibilities in two experiments (Boyer, Longo, and Bertenthal, in press). The first tested for spatial compatibility with an imitative cue as the imperative stimulus, and the second tested for imitative compatibility with a spatial cue as the imperative stimulus. The stimulus consisted of a left or right hand with fingers spread apart and appeared on a computer screen from a third person perspective. Participants were instructed to respond to either the left-right spatial location or the anatomical identity of the index or middle finger tapping downward (Figure 1).

Figure 1. Left panel depicts the left hand stimulus with the index finger tapping down. Right panel depicts the right hand stimulus with the middle finger tapping down.

Responses consisted of pressing a key with the index or middle fingers on the right hand. In the standard S-R compatibility task (henceforth abbreviated “S-R task”), **the responses were compatible with a task-irrelevant spatial stimulus when the left hand was presented** (see Figure 1). For example, participants instructed to respond to the spatial cue would press a key with their index finger when responding to the left tapping finger. In this condition, both the stimulus and response are index fingers, and thus the response is facilitated via automatic imitation. Likewise, participants instructed to respond to the imitative cue would, for example, press a key with their middle finger when responding to the middle finger tapping. In this condition, both the stimulus and response correspond to the right side, and thus the response is facilitated via spatial compatibility. **When the stimulus corresponded to a right hand, the**

Figure 2. *Upper panel.* Mean response times (ms) to spatially compatible and incompatible stimuli as a function of task in Experiment 1. *Lower panel.* Mean response times (ms) to imitatively compatible and incompatible stimuli as a function of task in Experiment 2. (Error bars represent  $\pm$  standard error of the mean.)

**responses were not compatible with a task-irrelevant stimulus.** In the Opposite S-R compatibility task (henceforth referred to as “OS-R task”), the task involved responding to the stimulus not presented on that trial (e.g., participants responded to a index finger with their middle finger). **Responses were compatible with a task-irrelevant stimulus that corresponded to the right hand, and incompatible with a stimulus corresponding to the left hand** (see Figure 2).

For the S-R task, Boyer et al. (in press) predicted similar results when the irrelevant stimulus was either spatially or imitatively compatible. By contrast, they predicted different results for the OS-R task. Switching instructions from a spatial S-R to a spatial OS-R task was first investigated by Hedge and Marsh (1975), who reported a “reverse compatibility effect”. Although there is no consensus concerning the underlying mechanism, most hypotheses suggest that the recoding of the stimulus generalizes to the task irrelevant stimulus responsible for spatial compatibility and hence facilitates responding to the incompatible stimulus. By contrast, Boyer et al. (in press) hypothesized that imitative compatibility involves a direct and independent mapping between the task-irrelevant imitative stimulus and the response as suggested by recent neurophysiological evidence (Rizzolatti and Craighero, 2004). Thus, no reverse compatibility effect is predicted.

The results from the two experiments supported these predictions. In the S-R compatibility tasks, participants’ response times were faster to the spatially and imitatively compatible stimuli than to the incompatible stimuli (see Figure 2). By contrast, in the OS-R tasks, participants’ response times to the spatially incompatible stimuli were faster than to the spatially compatible (i.e., reverse compatibility effect), whereas response times to the imitatively compatible stimuli were faster than to the imitatively incompatible stimuli (although this difference was not significant). The results from this latter experiment thus suggested that imitative and spatial compatibilities are not mediated by the same domain-general process.

Although the preceding results suggest that spatial and imitative compatibilities are mediated by different processes, it remains an empirical question as to whether the response differences are a function of different neural architectures or more simply a function of differences in the parameterization of the same architecture. The standard processing model for explaining S-R compatibility effects is a dual route model whereby responses are activated by an intentional route as well as an automatic route (Zorzi and Umiltà, 1995; Zhang, H., Zhang, J., and Kornblum, 1999). If the automatic route activates the same response as the intentional route, the response is facilitated. If, however, the automatic and intentional routes activate different responses, then the response is slowed down. In spite of sharing this general processing assumption, all dual route models are not the same. Some models are designed with some or all inputs mapped directly to the outputs, and other models are designed with a middle decision layer that selects the response (e.g., Sausser and Billard, 2002). In the current research, we hypothesized that the spatial compatibility task is mediated by the latter model, whereas the imitative compatibility task is mediated by a hybrid model (i.e., the automatic imitative route involves a direct mapping between input and output, but the controlled route involves a task-based mapping between the input and a middle decision layer). This latter model is consistent with recent theories suggesting that automatic imitation is due to a shared representation between the observation and execution of actions.

The purpose of the current investigation was to test this hypothesis with a computational model that was designed to simulate the empirical results from the previous study by Boyer et al. (in press).

### A PDP Model of Spatial and Ideomotor Compatibility Effects

We started with our previous computational modeling efforts (Boyer et al. 2009) and develop a new three-layered (input-hidden-output) connectionist network, with nodes at each layer representing the stimulus input, the S-R translation, and the response, respectively. We use simplified interactive activation and competition connectionist units (Rumelhart and McClelland, 1986) with change in activation over time is given by  $\Delta act/\Delta t = netin-$

$act(netin+decay)$ , where  $act \in [0,1]$  is the *activation* of the unit,  $netin \in [0,1]$  is the *sum of the weighted inputs* to the unit and  $decay \in [0,1]$  is a constant *decay factor*. The model consists of eight units: two input units, called *finger units*, representing the perceived index (“I”) and middle (“M”) input fingers; two input units, called *location units*, representing the left (“L”) and right (“R”) location of the perceived input fingers (depending on the stimulus hand); two *output units* representing the index finger in the left location (“IL”) and the middle finger in the right location (“MR”) of the right hand; and two hidden units (or decision units), called *SR units*, affecting the S-R translation between inputs and outputs (“SR-IL” and “SR-MR”). As in (Boyer et al. 2009), we start with a base model which shows the participant’s state before any task-based instructions and the task models which show the participant’s condition after a task-based instruction. The base model consists of automatic connections between input and hidden, and hidden and output units. The input finger (“I” or “M”) and spatial location (“L” or “R”) are mapped onto the requisite hidden unit (“SR-MR” or “SR-IL”) via the connections  $I \xrightarrow{a} SR-IL$ ,  $M \xrightarrow{a} SR-MR$ ,  $L \xrightarrow{a} SR-IL$ , and  $R \xrightarrow{a} SR-MR$ , respectively. These connections correspond to the compatible S-R translations between the imperative stimulus and the response, which we hypothesize are processed automatically by the hidden units presumably because they are overlearned and automatized. In addition to these automatic connections, we assume direct connections between input and output fingers that reflect the hypothesized direct matching pathways:  $I \xrightarrow{i} IL$  and  $M \xrightarrow{i} MR$  (note that there are no direct connections between input and output spatial locations). Lastly, hidden units are mapped onto corresponding output units via connections  $SR-IL \xrightarrow{a} IL$  and  $SR-MR \xrightarrow{a} MR$ .

Figure 3. The proposed neural network model: the base model consists of only the dashed connections; the bold connections depict the S-R compatible task-based connections for the index finger.

From the base model, we construct the task models by adding additional connections that depend on the task instructions. Specifically, we add connections between

input and hidden units: for the spatial compatibility models, we add task-based connections  $I \xrightarrow{t} SR-IL$  and  $M \xrightarrow{t} SR-MR$  reflecting that the imperative stimulus is the anatomical identity of the finger, and for the imitative compatibility models, we add task-based connections  $L \xrightarrow{t} SR-IL$ , and  $R \xrightarrow{t} SR-MR$  reflecting that the imperative stimulus is the left-right location of the finger. Furthermore, for the standard (S-R) mapping models we add task-based connections between hidden and output units  $SR-IL \xrightarrow{t} IL$  and  $SR-MR \xrightarrow{t} MR$ , while for the opposite (OS-R) mapping models we add task-based connections between hidden and output units  $SR-IL \xrightarrow{t} MR$  and  $SR-MR \xrightarrow{t} IL$  in which the controlled connection from the hidden unit crosses to the opposite output unit. This crossing is necessary given that the task instruction requires participants to select the opposite response to that selected in the standard mapping condition (i.e., either responding to the finger with the opposite identity or spatial location). Different from (Boyer et al. 2009), the current model has only excitatory connections (i.e., connections with positive values).

Inputs are applied to the model by fixing the netinput of the respective input units (e.g., “I” + “L”) at a particular value to indicate, for example, the perceived index finger in the left position). The input is applied on each cycle of the trial because participants are able to observe the stimulus finger until they respond. The state of the model is updated in discrete time steps (“cycles”) that correspond to 10 ms of real-time. Response selection is achieved whenever an output unit reaches the *action threshold* (i.e., the activation needed to perform a motor response by the finger). As such, the number of cycles computed from the introduction of the input (i.e., moving finger) until the action threshold is reached can be used to simulate the response times directly (e.g., 30 cycles correspond to 300 ms).

To minimize the number of free model parameters that can be used to fit models to the empirical data, we fix all base model parameters based on the study by Boyer et al., 2009. Specifically, we assume that all automatic connections  $\rightarrow_a$  and direct mapping connections  $\rightarrow_i$  have the same strength in all models, and they are set to a very low value of 0.001 (which is too low to generate any actions without task instructions, even if all input units are activated together). Moreover, we assume that the same decay factor of 0.05 for all computational units and also fix both the external input and the action threshold at 0.5. With those base model parameters fixed, we are left with the task-based connections as *free parameters* that can be used to fit the models to the empirical data.

## Model Fitting and Simulation Results

We start with spatial and imitative compatibility in the S-R condition. There are four free parameters in each condition

Figure 4. The simulation results of the proposed model for both compatibilities in the S-R and OS-R conditions.

corresponding to the input-to-hidden and hidden-to-output task connections, and we make the simplifying assumption that all task-based connections in the standard mapping models have the same strength. This assumption is plausible because both finger and location inputs require similar levels of encoding and integration followed by a similar S-R translation process regardless of whether the task instruction is to respond to the anatomical identity or location of the finger (Boyer et al., in press). Accordingly, we searched for a single positive value for all task-based connections that minimizes the *root mean squared error* for each model (*RMSE*). We found  $\rightarrow_t = 0.086$  to be such a value with *RMSE* = 12.28 ms, which is just above the model resolution of 10 ms necessary for simulating a compatibility effect.

The next step was to use the model parameters in the S-R condition to predict the results in the OS-R condition. As previously described, the hidden-to-output connections for the task-based processes reverse between these two layers because the correct response is opposite to the one cued by the stimulus. We assume that, because only the hidden-to-output connections are different from the S-R models, the OS-R models should use the same connection strength (0.086) as the S-R models for the input-to-hidden connections. Moreover, we assume that both hidden-to-output connections have the same strength for both outputs; but based on the results of Boyer et al. (in press) showing longer response times for recoding the spatial cue, we introduce different strengths for imitative vs. spatial compatibility conditions. Hence, we are left with only one free parameter  $SR-IL \rightarrow_t MR=SR-MR \rightarrow_t IL$  in each of the two opposite mapping conditions.

In order to fit this free parameter, we begin with the OS-R condition for imitative compatibility. Unlike the results for the spatial compatibility condition which showed a reverse compatibility effect, the empirical results for this condition were similar to those for the S-R condition. Given this similarity, we predicted that the same value of 0.086 should work for  $SR-IL \rightarrow_t MR$  and  $SR-MR \rightarrow_t IL$  in the OS-R

condition for imitative compatibility. Consistent with our hypothesis, this simulation was very successful with *RMSE* = 7.38 ms, which is less than the model resolution of 10 ms.

The situation was somewhat different for fitting the spatial compatibility model in the OS-R condition. Recall that this condition differed from the other three conditions in two ways: (1) the results revealed a reverse compatibility effect, i.e., response times were faster to the incompatible than to the compatible stimulus; and (2) the response times in this condition were significantly higher than in the comparable imitative compatibility condition (i.e., 571 ms vs. 454 ms). Hence, in order to model these two results, we made two predictions: (1) the reverse compatibility effect is a function of the model architecture, and therefore it should be unnecessary to change the connection strength of 0.0856 for  $SR-IL \rightarrow_t MR=SR-MR \rightarrow_t IL$  from the connection strengths used in the other conditions; and (2) a lower connection strength (less than 0.086) is required for  $SR-IL \rightarrow_t MR=SR-MR \rightarrow_t IL$  to fit the model to the significantly longer response times with a small *RMSE*.

In the first simulation of this condition, we did not change the hidden-to-output connection weight (set  $SR-IL \rightarrow_t MR=SR-MR \rightarrow_t IL=0.086$ ) which yielded a response time of 460 ms for the incompatible condition and a response time of 470 ms for the compatible condition. These results thus confirm our first prediction because they are consistent with a reverse compatibility effect. In the second simulation we lowered  $SR-IL \rightarrow_t MR=SR-MR \rightarrow_t IL=0.083$  by about 3%, which yielded a response time of 560 ms for the incompatible condition and a response time of 580 ms for the compatible condition. In contrast to the previous simulation, these results revealed not only a reverse compatibility effect but also a very small *RMSE* = 4.12, thus supporting our second prediction.

Several points are worth noting about the above modeling results. First and foremost, the current models are capable of capturing the reversed spatial compatibility effect in the

empirical data that Boyer et al. (2009) failed to capture. At the same time, the current model is simpler than the one presented in Boyer et al. (2009) because it has fewer nodes and fewer connections, does not use any inhibitory connections, and thus has overall fewer parameters. And

finally, the fits we obtained here are better than the fits in Boyer et al. (2009). The fact that spatial and imitative compatibilities in the OS-R condition required separate models is theoretically significant. This result thus provides an important source of evidence for concluding that the two compatibilities are not mediated by the same processes.

### Testing the Generalizability of the Model

Given that the model succeeded at capturing the data from Boyer et al. (in press), we sought to test its generalizability as a means of providing further evidence that spatial and imitative compatibilities are not mediated by the same processes. Recently, Catmur and Heyes (2010) conducted a related study testing the effects of spatial and imitative compatibilities on response times. In this study, participants responded to a discriminative cue with an abduction of either the index or little finger of their right hand. On each trial, a left or right hand was displayed initially in a neutral position with fingers spread apart and the outline of a small white circle appearing equidistant between the tips of the index and little fingers. Participants were instructed to respond as quickly as possible to the circle changing to orange or purple by abducting their index or little finger depending on the task instructions. Simultaneous with the appearance of the discriminative cue, the index or middle finger of the stimulus hand was abducted. By varying whether the stimulus corresponded to the left or right hand, it was possible to independently manipulate imitative and spatial compatibility, such that both compatibilities were present, only one, or neither.

To allow our current model to simulate the Catmur and Heyes (2010) task, we add two additional color nodes (“O” for “orange” and “P” for “purple”) together with task-based connections  $O \rightarrow SR-IL$  and  $P \rightarrow SR-MR$  to the two hidden nodes “SR-IL” and “SR-MR”, respectively, in the base model to reflect the requirement to abduct the little finger (“little finger”) for the orange stimulus, and the index finger (“index finger”) for the purple stimulus or vice versa (note that we can re-use the “middle finger” node for the “little finger”). We hypothesize that our model should also be able to simulate the results from this study with only minor adjustments. Keeping the task-based connections while increasing the automatic connections (to 0.003) and lowering the direct mapping connections (to 0.0001), we get a result (with a small RMSE of 7.07ms) that very closely captures the Catmur and Heyes (2010) data (see Figure 5). This result confirms that our model is not limited to simulating results from only one specific experiment. It should be noted, however, that we do not simulate all results from the Catmur and Heyes (2010) experiment, because they also investigate the time course of the compatibility effect during

the trial. In order to model these within trial timing effects, it would be necessary to design a stochastic model which is currently in development, but it is premature to report any results from this model.

Figure 5. The simulation results of the model for the Catmur and Heyes (2010) experiment (“SC”=“spatial compatible”, “IC”=“imitative compatible”, “SI”=“spatial incompatible”, and “II”=“imitative incompatible”).

### General Discussion

There are three principal conclusions from this investigation: (1) A computational model was presented that was successful in simulating the effects of spatial and imitative compatibilities in three separate conditions. (2) Unlike previous dual route models for explaining stimulus-response compatibilities, spatial and imitative compatibilities did not conform to the same architecture (i.e., imitative compatibility included a direct input-output connection, whereas spatial compatibility did not include this direct connection). (3) The finding that spatial and imitative compatibilities were modeled differently provides converging evidence that these two compatibilities are mediated by different processes.

A legitimate question is, therefore, whether the model would have been equally successful if we reversed which stimulus dimension was simulated with direct connections. Figure 6 shows the model with direct input-output connections for spatial, but not for imitative compatibilities. As can be seen, the model is just the mirror image of our previous model in the S-R conditions and thus fits the empirical results almost as well (with a slightly larger RMSE=15.52). In the OS-R condition, however, the model differs significantly from the empirical results, showing the exact opposite relations (as indicated by the two ovals in Figure 6). Not surprisingly, the RSME=38.87 for the OS-R condition is significantly higher than for the previous model with the direct imitative connections (RSME=7.12). It thus appears that these direct connections are necessary for predicting the imitative compatibilities in the OS-R condition. Given these results, we also investigated whether adding to our model direct connections for spatial compatibility improved the fit.

Figure 6. The simulation results of the model with no direct imitative, but direct spatial connections for both S-R and OS-R conditions. The ovals depict the two conditions in which the model predicts the opposite effects from the empirical data.

Preliminary experiments show that the addition of direct connections between the location and output nodes results in does even worse (without lowering of the task-based connections) in the S-R condition (with RSME=21.27 compared to RSME=13.99 for our previous model). However, as with the model including only direct spatial connections, this new model failed to match the empirical data in the reverse spatial compatibility condition, with an overall RSME=37.89 for both OS-R conditions. Hence, neither models with only direct spatial nor models with direct spatial and direct imitative connections are capable of matching the empirical data in the OS-R conditions as well as our proposed model under the given parameter assumptions.

## Conclusions

In this paper, we introduced the first computational PDP model that can be fit to human data dissociating spatial from imitative compatibilities *and* can be used to make predictions about related tasks. While the results are constrained by the chosen constants and the modeling process, the comparison with alternative model architectures together with the model's ability to predict performance in a related, yet different task, are an encouraging step towards a full-fledged investigation of model parameters and model architectures that might be able to account for the empirical differences between imitative and spatial compatibility effects in a great variety of experimental paradigms.

## Abstract

Development is about change over time. Computational models have provided insights into the developmental changes seen in different cognitive phenomena, including within the domain of word learning. The present paper uses a computational model to investigate the interdependencies between the emergence of different word learning biases. This model allows investigation of how the emergence of the shape bias influences novel noun generalization to two other types of items. The results suggest that the emerging shape bias for solids can either strengthen or weaken other types of biases depending on the strength of the cues to solidity or non-solidity; further, these results make predictions about children's biased word learning over time.

**Keywords:** Computational models; neural networks; trajectories; word learning; shape bias.

## Introduction

Computational models have proven to be an important tool for investigating many issues within cognitive development (e.g., Munakata & McClelland, 2003). Such models can provide insights about the mechanisms that underlie learning patterns seen across childhood. In the domain of word learning, various models have been used to investigate fast mapping and the taxonomic shift (Mayor & Plunkett, 2010), variability effects in learning phonetically similar words (Apfelbaum & McMurray, 2011), task effects in novel noun generalization (Samuelson, Schutte, & Horst, 2009), and word learning at different levels of abstraction (Xu & Tenenbaum, 2007). In this paper we focus on using connectionist models to examine developmental trajectories in word learning. This approach has the potential to guide novel and testable predictions about children's language development.

This paper employs a computational modeling approach to investigate the emergence of word learning biases that support early language acquisition. This approach allows us to analyze in detail how different word learning biases interact and influence one another over the course of word learning. For example, does a later emerging bias build onto and benefit from an earlier bias, or is there a period of conflict as new knowledge is assimilated with prior

knowledge? Our results indicate that different biases do interact, and the emergence of one bias can either strengthen or weaken other biases depending on the strength of cues provided in the learning context. These results allow us to make predictions about the timing of children's word learning and generalization as biases emerge.

## Word Learning Biases

One of the reasons that children are such skilled language learners is because of biases. In the context of word learning, biases are constraints on the range of things that children will consider in deciding what a new word refers to. Rather than assuming that any word can be used to label any item, children exhibit principled patterns of behavior in the ways in which they learn words. The main constraint we will focus on in this paper is found within the domain of noun learning: the shape bias. The shape bias refers to young children's tendency to generalize newly learned nouns to other objects based on similarity in shape (Landau, Smith, & Jones, 1988). That is, if a child is taught a novel name for a novel solid object, he or she will extend that name to other objects that match the original in shape, even if that shape match differs in texture, color, or size. Children show a reliable shape bias by 2 years of age (Samuelson & Smith, 1999).

A related phenomenon in noun learning is the material bias. While the shape bias is seen in children's generalization of labels to solid objects, the material bias concerns the labeling of non-solid substances. The material bias has been found using the same novel noun generalization (NNG) paradigm typically used in studies of the shape bias. Children taught a novel name for a novel non-solid substance tend to generalize that name to other non-solids that match the original in material rather than to non-solids matching in features like shape and size but made out of a different material (e.g., Soja, 1992; Soja, Carey, & Spelke, 1991). The material bias is typically seen slightly later than the shape bias, at 3 years of age (Yoshida & Smith, 2005).

Altogether, the evidence suggests that over the first years of life children develop preferential attention to different

features of items in noun learning, first to shape in naming solid objects and then to material in naming non-solid substances. This raises the question of whether and how these biases interact with each other. Does development of the shape bias earlier on have any impact on the material bias? Research looking at naming and generalization of other, ambiguous kinds of items hints at this possibility. For example, deformable items usually have a characteristic shape, but are also often categorized as being similar to each other in material (e.g., an item such as *towel*; Samuelson, Horst, Schutte, & Dobbartin, 2008). Previous research shows that young children categorize deformable items based on similarity in material when they are not labeled, but categorize based on similarity in shape when the items are labeled (Samuelson & Smith, 2000). Samuelson and colleagues (2008) hypothesize that this behavior represents an overgeneralization of the shape bias. This suggests that the emergence of the shape bias can influence how children learn and generalize names for other, more ambiguous kinds of items as well.

### The Emergence of Biases

Although there is some debate over the origin of word learning biases (e.g., see Samuelson & Bloom, 2008), there is strong evidence to suggest the link between vocabulary growth and the emergence of word learning biases. This has been explored especially in relation to the shape bias, with several pieces of evidence suggesting interactions and feedback between attending to shape in the context of learning names for solid objects and overall word learning.

First, there is evidence that the emergence of the shape bias influences subsequent word learning. For example, Smith, Jones, Landau, Gershkoff-Stowe, and Samuelson (2002) intensively trained 17-month-old children on labels for novel shape-based categories. The children exposed to this training not only developed a shape bias earlier than is typically seen, they also showed a dramatic increase in vocabulary size compared to a control group. These results suggest that the development of the shape bias accelerates children's learning of object names outside of the lab.

Evidence for a feedback relationship between word learning and the emergence of the shape bias comes from a study by Gershkoff-Stowe and Smith (2004). In this study, children were longitudinally tested on their attention to shape in generalizing a novel label. The researchers also collected diaries tracking children's vocabulary growth. The results showed that children's attention to shape increased as the number of nouns in their vocabularies increased.

Together these studies suggest an interesting pattern of interactions between language acquisition and the emergence of word learning biases. As children add more nouns to their growing vocabularies, they show an increasing preference to attend to shape in the context of naming solid objects. This preference to attend to shape in turn facilitates subsequent word learning. This leaves open the question of how different biases may interact over the

course of language development. Modeling word learning offers a unique way to investigate this question.

### Modeling Word Learning & Biases

Computational models of word learning have been used to investigate the conditions that support word learning biases. For example, Colunga and Smith (2005) trained a network with a vocabulary structure of half solid objects characterized by shape and half nonsolid objects characterized by material—a vocabulary structure which should directly promote the development of shape and material biases. Results of the virtual analog of the NNG task confirmed this prediction in that the network showed a shape bias for solids and a material bias for nonsolids. In a second simulation, they trained the same network on a realistic early vocabulary, structured like that of a typical 30-month-old. The earliest nouns that children typically learn are dominantly comprised of solid objects characterized by shape (e.g., *ball*, *spoon*), and include fewer non-solid substances characterized by material. The typical early noun vocabulary also includes types of items that can be characterized by both shape and material. When trained on this more complex vocabulary structure, the network again treated novel test items in ways consistent with shape and material biases. Colunga and Smith (2005) also reported behavioral data with young children confirming the predictions of this network. More recently, Colunga and Sims (2011) used the same kind of network to successfully predict differences in novel noun generalization patterns between early- and late-talker children.

These studies show that computational modeling is a powerful tool for exploring the emergence of word learning biases. However, no one has yet used this approach to investigate the relationships between different biases as they emerge over the course of word learning. Our approach offers a new perspective by modeling different word learning biases together on a developmental timescale.

### Approach and Overview

Our approach is to train a network on a typical early child vocabulary and then test it on generalization of three different kinds of items over the course of word learning. The goal is to see how the shape bias emerges over word learning and how the emergence of the shape bias impacts generalization performance on other kinds of items. To test for a shape bias, we implement a virtual NNG task by exposing networks to novel solid items and seeing if they treat those alike in shape more similarly than those alike in material (as in Colunga & Smith, 2005). We also test the network on two types of novel non-solid items: simply-shaped, clearly material-based non-solids and complex-shaped, ambiguous non-solids. An example of a simply-shaped nonsolid would be a glob of paint. While it can take on slightly different shapes, it always maintains its “blob-like” shape. Simply-shaped non-solids are inherently material-based because there is more variation in the material than in the shape, making the material of an item a

more useful cue in classification. Complex-shaped, ambiguous non-solids, on the other hand, can take on virtually any shape, e.g. paint smeared in the shape of a peace symbol. In this case, shape and material have equal variability and either one could be a cue to classifying an item. We explore whether the network develops a material bias for these types of non-solids, and whether that development depends on the emergence of the shape bias for solids.

## Simulation

### Method

Computational models use the Leabra algorithm (Local, Error-driven and Associative, Biologically Realistic Algorithm), which combines Hebbian and error-driven learning. Weights are adjusted based on correlations between activation units and feedback of errors through back propagation (O'Reilly et al., 2012).

**Architecture** The architecture is adapted from Colunga and Smith (2005) and is implemented as shown in Figure 1. Words are represented discretely and are input on the Word Layer. Referents are represented as distributed patterns over several dimensions on the Perceptual Layer. For example, the shape and material of an object (say the roundness of a particular ball and its yellow rubbery material) are represented by an activation pattern along the Perceptual Layer, with 12 units for shape and 12 units for material. Solidity is represented discretely; one unit stands for Solid and another for Non-Solid. Finally, there is a 25 unit Hidden Layer that is connected to all the other layers and to itself. The Hidden Layer serves as the bridge between the Word Layer and the Perceptual Layer and it is where learning occurs. Learning progresses as internal representations, or weights, update and form links between the other two layers.

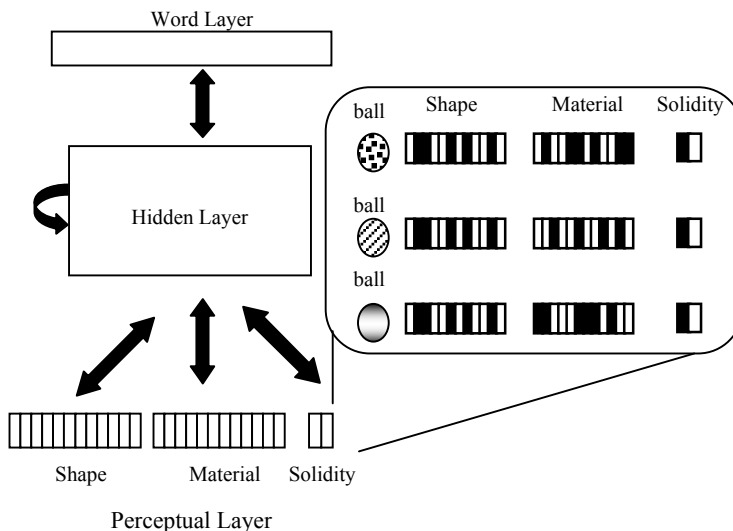

Figure 1: Architecture of the network and example input patterns.

Table 1: Noun category proportions used to create the input vocabulary structure. Beneath each proportion is an example noun belonging to that category.

	Shape	Material	Both
Solid	52% <i>ball</i>	10% <i>cheese</i>	12% <i>crayon</i>
Non-solid	4% <i>bubble</i>	16% <i>glue</i>	6% <i>jeans</i>

**Input Patterns** The input patterns consisted of training and testing patterns. The training patterns were structured to capture the same correlational structure as the vocabulary of a typical 30-month-old child (Fenson et al., 1993). The structure of this training input was based on that used in Colunga and Smith (2005). Using adult judgments, nouns were categorized by both solidity (either solid or non-solid) and characteristic feature (either shape, material, or both). The structure of the typical early noun vocabulary could then be expressed as proportions of each type of category. See Table 1 for the 6 categories and proportions used in the current study. The network in this study was trained to learn 50 noun representations, designed to have approximately the category structure of the typical 30-month-old's vocabulary. Note that these 50 noun representations are word inputs to the network and do not necessarily correspond to 50 nouns that a child learns.

The test input patterns consisted of three kinds of items represented along the Perceptual Layer: solids, simply-shaped non-solids, and complex-shaped non-solids. Test patterns were made up of triplets of novel items: an exemplar and two choice items.

For solid test items, this pattern was instantiated by manipulating activation across all shape and material units of the network. For clear non-solids, half of the shape units were kept constant to capture the fact that non-solid substances are typically seen in simple shapes like smears and splashes.<sup>1</sup> That is, these simply-shaped, clear non-solids had some variability in the shapes they could take on, but also had some imposed limitations. Finally, the ambiguous non-solid test patterns were represented by manipulating activation across all of the shape and material units. This type of non-solid test pattern is called ambiguous because, unlike other non-solids the network was exposed to, they can take on more complex shapes and thus be construed as having a characteristic material or a characteristic shape. Therefore, testing involved generalization to novel solid and simply-shaped, non-solid items as well as generalization to a new, ambiguous type of non-solid item.

**Progression of Word Learning** To chart the course of bias development, we tested the network at multiple points throughout word learning. Weights were recorded at initialization, every five words from 0 to 30 words learned, and every ten words from 30 to 50 words learned. The

<sup>1</sup> This method for simplifying the shapes of non-solids was also used in the training input patterns.

endpoint of learning was recorded as either asymptotic performance of learning all 50 words, or at the end of 500 epochs of training. This resulted in ten checkpoints along the trajectory of word learning. Although other measures such as duration of training could capture how much a network has learned, we used number of words learned because this is the key factor driving the development of biases.

**Training.** On each trial of training, a word was paired with a referent. The patterns associated with each word were determined based on which noun category that word was meant to represent. For example, a word for a solid item characterized by shape (like a ball; see Figure 1) should be used to label things that are like each other in shape but differ from each other in material. To simulate this pattern, we randomly selected an input vector to represent, for example, ball shape. On individual training trials, we paired that shape pattern with the label *ball* and a randomly selected material pattern. Therefore over multiple training trials, a word for a solid item characterized by shape would be represented by the same shape but different material patterns. We did this for each of the 50 nouns in the training set. This part of the simulation was intended to put into the network the lexical knowledge that a typical child would bring to the laboratory NNG task.

**Testing** Following training, the next step was to identify what sort of word learning biases each run of the network had developed. We addressed this question with a virtual version of the NNG task. We presented the network with three NNG tasks, one for each of the three types of items: solids, clear non-solids, and ambiguous non-solids. On each test trial of these tasks, we presented the network with a triad of novel entities (one at a time) on the perceptual layer. The triad consisted of an exemplar and two choice items, one matching the exemplar in shape only and one matching in material only. The only difference between the trials for the clear non-solids and those for ambiguous non-solids was that for clear non-solids, the material-matching choice item had a simplified pattern along the shape layer, as discussed in the input patterns section. For each of these three inputs, we recorded the resulting pattern of activation on the hidden layer. This is a measure of how the network represents these items. If the network emphasizes the shape of the item, then the similarities of the internal representations for the exemplar and its shape matching choice should be *greater* than the similarity of the internal representations for the exemplar and the material matching choice. If this same relationship is *less*, then the internal representations highlight the material of the items. We used these similarities along with Luce's choice rule (Luce, 1963) to calculate probability of choice in order to predict performance in the NNG task.

## Results

We averaged over 10 runs with different initial random weights. First we looked at the network's test output across the entire course of learning. As shown in Figure 2, the network preferred the shape match choices at test to different extents depending on both the solidity of the item presented and the size of its vocabulary at that point. For example, before training, the network showed no preference for either the shape match or the material match test choice for solid items, tending to choose the shape match about half the time ( $M = .50$ ,  $SD = .02$ ). In contrast, by the end of training the network chose the shape match for solid items about three quarters of the time at test ( $M = .78$ ,  $SD = .04$ ).

On the other hand, while the network started at a similar state for complex-shaped, ambiguous non-solids, it showed a different preference by the end of training. Specifically, the network began with no preference for shape or material, but developed a shape preference for these non-solids, albeit to a lesser extent than it did with solid items ( $M = .62$ ,  $SD = .03$ ). This pattern shows an overgeneralization of the shape bias to this particular kind of non-solid item.

Figure 2: Mean proportion of shape match choices at test for each kind of test item. Error bars represent standard error.

Still another pattern was seen in how the network treated simple-shaped, clear non-solids at test. In this case, the network actually began with a preference for material, choosing the shape match test choices slightly but significantly less than 50% of the time ( $M = .47$ ,  $SD = .01$ ,  $t(9) = -8.31$ ,  $p < .001$ ). This inherent material bias was present at initialization due to the input structure of the clear non-solids items. Recall that for this type of item, half of the shape units were kept constant across all of the input. Because of this, at the time of initialization the networks had less information about variations in shape on which to base representations. Instead, the networks harnessed the relatively richer material information immediately available about clear non-solid items, and thus showed a slight preference for this feature initially. However, by the end of learning the initial preference for material was gone ( $M = .50$ ,  $SD = .02$ ). What caused the network to lose this early preference for material in the context of clear non-solids? And more specifically, did it have anything to do with what

was concurrently being learned about solid items? To get at this question, we next focused our analysis on the time window in which the shape bias emerged in learning.

Figure 3: Mean proportion of shape match choices at test for solids and ambiguous non-solids immediately before and after the emergence of the shape bias for solids.

Identifying the point in learning at which the network first developed a shape bias involved several steps. First we examined the output of each of the ten runs and picked out when in learning the network chose the shape match test choice for solid items greater than 55% of the time.<sup>2</sup> This happened on average around the time the network had learned 15 words from the training set. The next step was to identify how this point of emergence of the shape bias in solids affects the network's behavior concerning the two kinds of non-solids. We isolated the closest time points in learning both preceding and following the emergence of the shape bias. Using this focused time window, we examined how the network treated each type of non-solid item in relation to solid items as the shape bias for solids emerged.

To examine the interaction between the emerging shape bias and the network's choices among complex-shaped, ambiguous non-solid test items, proportion of shape choices were submitted to a 2 (test item type: solid or ambiguous non-solid)  $\times$  2 (time point in learning: before or after the emergence of the shape bias) mixed design analysis of variance (ANOVA).<sup>3</sup> This analysis yielded a significant main effect of time point,  $F(1, 30) = 13.41, p = .001$ , with no other significant effects. This shows that as the shape bias for solids emerges in the course of learning, a similar bias develops for ambiguous non-solids (see Figure 3), suggesting an overgeneralization of the shape bias to ambiguous non-solids. Further, this shape bias for both types of items increases over the time window of interest.

Next we examined the interaction between the emerging shape bias and the network's choices among simply-shaped, clear non-solid test items. Proportion of shape choices were

submitted to a similar 2 (test item type: solid or clear non-solid)  $\times$  2 (time point) ANOVA. This analysis yielded main effects of both test item type ( $F(1, 30) = 25.47, p < .001$ ) and time point ( $F(1, 30) = 11.14, p < .01$ ). These main effects are qualified by a significant interaction between test item type and time point in learning,  $F(1, 30) = 8.73, p < .01$ . As can be seen in Figure 4, as the shape bias for solids emerges, the network's preference for shape choices for clear non-solids also increases, however the nature of these changes differs between item types. In fact, the network shows a preference for material test choices for clear non-solids, even just after the emergence of the shape bias for solids. Although this preference for material diminishes somewhat over the time window in question (as shown by an increase in proportion of shape choices), it does not do so at a rate proportional to the growth of the shape bias for solids. This suggests that the emergence of the shape bias may have a slight diminishing influence on the material bias for clear non-solids.

Figure 4: Mean proportion of shape match choices at test for solids and clear non-solids immediately before and after the emergence of the shape bias for solids.

Finally, to check that these patterns were specific to the time window surrounding the emergence of the shape bias, we ran the same analyses for the immediately following time window. The only effect that reached significance was a main effect of item type between solid and clear non-solid test items,  $F(1, 32) = 37.62, p < .001$ . As in the above analysis, this reflects an ongoing difference in the extent of shape choices that the network made in the context of these two types of items. The fact that no other effects were significant supports the argument that the preceding results are specific to the time window in learning immediately surrounding the emergence of the shape bias.

## Discussion

The current study investigated the dynamics involved in the development of the shape bias for solid items and learning about other kinds of items in early language acquisition. We found that the emergence of the shape bias for solids led to either an overgeneralization of the shape bias or a diminishment of the material bias, depending on the

<sup>2</sup> 55% was chosen as the threshold for emergence because at this value the network chose shape matches reliably greater than chance across the ten runs,  $t(9) = 12.54, p < .001$ .

<sup>3</sup> This type of analysis was chosen following Colunga & Smith (2005) in their analyses of similar networks.

strength of the cues to solidity or non-solidity provided by the test items, depending on the type of test item used.

First, for complex-shaped, ambiguous non-solid test items, we observed an overgeneralization of the shape bias. This is consistent with findings that 3-year-old children overgeneralize the shape bias in extending names to deformable items (Samuelson et al., 2008). This suggests that for ambiguous categories, the word learning bias that is already established, typically the shape bias, takes precedence and guides generalization.

Second, for simply-shaped, clear non-solid test items, the material bias diminished as the shape bias for solids developed, although it did so at a slower rate compared to the growth of the shape bias. This suggests that the material bias for clear non-solids was more resistant to the influence of the developing shape bias, perhaps in part due to the inherent material preference for these items. This inherent bias was due to the structure of the input itself, but a similar early material bias has also been seen in children if they are tested with simply-shaped non-solid substances on the NNG task (Colunga & Smith, 2005).

The mechanisms driving the observed changes in bias learning and development in our networks speak directly to possible mechanisms in children. The current work suggests that the network can mainly develop one bias at a time, which would explain why as the shape bias for solids takes off, the network also shows a growing preference for shape for the two other types of items. If this is the case, we would predict that as the network continued to train on more words, the material bias for non-solids would come online (as seen in children) and cause a dip in the established shape bias for solids. However, by this time the shape bias for solids would be well established and thus largely resilient against the network's shift to focusing on material. After enough exposure to the vocabulary structure, we would expect the network to have acquired both a shape bias for solids and a material bias for non-solids, as is seen in children later in language development.

This work could be extended to make predictions about and map to specific places of bias emergence in individual children's word learning. By using longitudinal MCDI data from individual children, one could use networks to analyze the development of language biases in early- and late-talkers (as done in Colunga and Sims 2011), looking specifically at how the emergence of certain word learning biases affects other biases over time. These biases could show different patterns of interaction among early- and late-talkers. In sum, this work opens the door for further modeling and can make novel, testable predictions about the development of children's word learning.

## Abstract

Perceptions influence the way we act in our environment based upon judgments assessing required efforts to perform an action and the availability and demand for immediate action on an object (Proffitt, 2006B). Social and physical anxiety has been shown to distort perceptions of depth and perceptions of object size (Stefanucci et al., 2008; Cañal-Bruland et al., 2010). Relatively little work, however, has explored the potential role of depth perception in abstract reasoning tasks (Landy & Linkenauger, 2010). In Experiment 1, the relationship between depth perception and the order of actions taken to simplify arithmetic expressions was investigated by manipulating apparent distances of arithmetic operations of high and low syntactic precedence. When the high precedence operations appeared to be closer to the participant, expressions were solved more quickly than when low precedence expressions appeared to be closer. Experiment 2 explored the whether the affordance of abstract actions conversely impacted perceived distance by asking participants to make distance judgments to multiplication and addition operations. Experiment 2 found no impact of anxiety about mathematics on perceived distance. However, effects resulting from condition assignment were found to influence perceived distances, as well as solving strategy. We interpret results in terms of attention, which we speculate plays a key role moderating both ordering behavior and perceived distance.

**Keywords:** Perception; Anxiety; Attention

## Introduction

The basic purpose of perception is to guide sensible action. Specifically, perception functions as a tool that informs and guides actions (Proffitt, 2006A). Perception involves consideration of the necessary efforts required to perform an action, which in turn may bias judgments of object size and proximity. For instance, perceived distance of an object is more than simple metric distance. Participants carrying a heavy backpack estimate the slant of hills to be steeper than those not wearing backpacks (Proffitt, 2006B). Likewise, simply intending to act on an object could make it seem closer Witt & Proffitt (2005). Witt & Proffitt (2005) found that athletes playing well reported a softball ball as being bigger than its actual size and therefore closer. Their ability to hit the ball was correlated with their batting average, demonstrating the relationship between perceptions of object size and performance when acting on that object. Perceptual phenomena like these indicate that perception relates the body and goals to the opportunities and costs of acting in the physical environment.

Although the connection between concrete physical action capabilities and depth perception is well documented, much less work has explored the relationship between perceived depth and non-concrete behaviors. There is evidence that anxiety also influences perception (Proffitt, 2006A). For instance, participants with a fear of heights judge hills to be steeper than do those who are less afraid (Stefanucci et al, 2008). According to Teachman et al (2008), fear of heights is associated with perceptual biases in judging heights, implying that an individual's emotional state influences what is seen, perhaps because it affects perceived costs, such as the cost of falling down a steep hill.

Anxiety not only distorts perception in the sense that distances appear farther and angles steeper, but also by altering the appearance of an object's size. Cañal-Bruland, Pijpers, & Oudejans (2010) studied the relationship between anxiety and depth perception, while also taking into consideration perceptions of object size. Participants were asked to throw darts at a target from a position on a rock wall. Cañal-Bruland, et al. found that the low anxiety group performed better and saw the target as bigger. However, these findings are limited to perceptions related to actions in the physical world.

Even less is known about cases in which the action itself is abstract or non-physical. In the case of abstract calculation, since all actions are in principle equally easy to perform, the logic of perceived energetic cost per se does not predict any relationship between depth and intentions to act. However, mathematical rules specify that certain operations are to be performed before other others. Particularly relevant for the studies reported here are the order of precedence rules, which require that multiplications be executed before additions. As a result, some operations demand action before others, making it possible to vary the relative availability of actions. Furthermore, since the actions do not depend on reach distance, any action lies within the action boundary (Fajen, 2005). Landy & Linkenauger (2010) found a relationship between the availability of computational actions in compound arithmetic expressions and judgments of depth. The study explored judged depth of terms, and indeed found that participants in a forced-choice task preferred to align depth and precedence; furthermore, in a face-vase illusion in which sub-expressions of mathematical equations were superimposed onto a face-vase illusion, when the times sign was over the vases, participants reported seeing the faces less often than when the times sign was over the faces. These perceptual effects can be explained by the

affordances of immediate action associated with the times sign as a result of taking precedence when using order of operations in solving arithmetic expressions. The current work builds on Landy & Linkenauger (2010) by considering whether perceived (rather than judged) distance interacts with the availability of concrete action

Visual attention also plays a significant influence on action-specific perception and performance. In their study, Cañal-Bruland, Zhu, van der Kamp, & Masters (2011) explored this relationship through a golf-putting task that manipulated the target-directed visual path. They found that participants receiving full visual access to the target and who putted more successfully estimated the target circle to be bigger than their less successful counterparts. Thus, the results of this study have shown that visual attention influences perceptions object size, but only for objects of an intended action. The relationship between anxiety and depth perception is abstract when attentional influence is taken into consideration. The current study aims to further explore attention as a moderating variable in the relationship between math anxiety and depth perception.

Math anxiety is defined by a strong tendency to avoid math, which leads to lower competency levels in math compared to those without math anxiety (Ashcraft, 2002). Hoffman (2010) posits that anxiety is a common impediment to learning in college students. Anxiety has shown to impede working memory processes involved with problem-solving efficiency, especially for women. Implications from prior research suggest that more needs to be done in order to understand the perceptual difficulties associated with math anxiety, especially if research can identify attention as a target for future interventions.

The purposes of the current studies were as follows: first, to establish whether the effect on judgments of apparent distance in pictures reported by Landy & Linkenauger (2010) generalized to perception in physical situations and second, to evaluate the influence of anxiety in distorting perceptions of depth in abstract situations.

Figure 1: The stimuli used in Experiment 1. In this congruent problem, the times sign (which is high precedence) appears to be closer to the subject.

## Experiment 1

### Participants & Procedure

Thirty members of the University of Richmond community were given partial course credit in exchange for participation.

Participants sat in front of a computer. Participants were shown 128 simple arithmetic problems, and were instructed to state the solution to the problems out loud. Before beginning, participants were reminded of the order of operations through direct instruction and an example, and were explicitly instructed to ignore any irrelevant images or visual structure. Responses were recorded by microphone and analyzed using CheckVocal (Protopapas, 2007).

All trials involved single digit operands, and were of one of two forms:  $a+b \times c$  or  $a \times b+c$ . Correct solution values ranged from 13 to 76.

The first 8 trials were practice trials. In these trials, problems were presented against a white background. In the remaining 120 trials, problems were presented against a background image intended to affect the apparent depth of the operators and operands. In this image (see Figure 1), stimulus problems appeared to be placed on a set of pillars, which varied in whether the left operator appeared closer (*left-closer* condition), or the right (the *right-closer* condition).

We hypothesized that problems would be solved more easily when the high-precedence operation appeared to be closer to the participant (called *congruent* problems). Following comparable results in the manipulation of spacing cues (Landy & Goldstone, 2010) we expected the alignment of precedence and distance cues to selectively influence order of operation reversals and operation errors (e.g., performing a multiplication instead of an addition), and to affect correct-trial response time.

### Results

Because trial RTs were substantially non-normal the median response time for each condition was calculated for each subject, and subjected to a standard ANOVA. Pillar and operation structure functioned as independent variables (see Table 1). Neither main effect was significant (pillars:  $F(1,28)=0.04$ ,  $p \sim 0.85$ , operations:  $F(1, 28)=1.2$ ,  $p \sim 0.3$ ); the interaction was significant and in the predicted direction ( $F(1,28)=10.4$ ,  $p < 0.01$ ).

Mean accuracy was 0.90 (Min=0.79, max=1.0). Participants made very few order of operations errors and operation errors: together, these made up just 2.9% of responses. There was no difference between problems that aligned pillars and operation structure and problems that misaligned them. The error rate was 0.1 (SE=0.01) on incongruent problems, and 0.06 on congruent problems (SE=0.01) on congruent problems. A logistic regression over operation order and pillar structure revealed neither a main effect (operations:  $z=0.4$ , pillars:  $z=0.16$ , all  $p$ 's  $> 0.5$ ), nor an interaction between the two ( $z=0.5$ ,  $p \sim 0.6$ ). Results

Table 2: Mean response time for accurate trials in Experiment 1 (Errors are standard errors).

Leftmost operation	Closer Pillar	
	Left	Right
Plus	2619 (127)	2516 (111)
Times	2465 (129)	2554 (131)

were nearly identical when just order and operation errors were considered: The mean rate of operation errors and order errors was 0.03 (SE=0.007) and 0.028 (SE=0.007) for congruent and incongruent problems, respectively; there was no difference between these by a logistic regression over pillar structure and operation (pillar  $z = -1.1$ , operation order = -0.1, interaction  $z = -0.5$ , all  $p$ 's > 0.61).

## Discussion

Apparent distance did, as predicted, influence the execution of basic arithmetic problems. Despite the equal availability and readability of all terms in these problems (i.e., all problems were presented on identical local backgrounds, at identical sizes), problems in which high precedence problems were apparently nearer to the participant were solved more quickly than those in which the reverse was true. This suggests that reasoners use cues about physical structure when making abstract decisions such as operation ordering. Experiment 1 indicates a bidirectional relationship between apparent distance and arithmetic ordering.

In other similar work (e.g., Landy & Goldstone, 2010), we have typically observed both accuracy and response time effects. One difference between those and these was that the rate of errors in this study was very low overall (just 10%), and the rate of errors expected to be related to operation order was even lower (just 2.9% overall). The population of students in the current study was generally efficient at basic arithmetic. This fact, together with the direct reminder to follow the order of operations, may have shielded participants from making many direct strategic errors when solving the expressions.

## Experiment 2

Experiment 2 explored the relationship between perceived distance, action affordance, and experienced anxiety in an abstract domain--arithmetic. Participants judged the distance to specific symbols inside an arithmetic expression, which either did or did not afford immediate action. We hypothesized, first, that participants who knew the order of operations would judge times signs as closer than plus signs, since in unparenthesized expressions with multiple operations multiplications afford more immediate action than additions do. We explored whether demonstrations that anxiety distorts perceptions of action affordances would generalize to abstract actions and situations.

## Participants

The 32 participants of this study were from the Richmond community between the ages of 18 and 30. They were recruited through flyers posted around the University of Richmond campus, as well as, through weekly online campus announcements.

## Apparatus and Materials

**Experimental Room.** The room was set-up with two identical tables (137 cm x 76 cm) joined at a corner, forming an L-shape. The participant's chair was positioned at the corner of these tables facing the wall. Both tables were positioned approximately 23 cm from the wall. The front legs of the chair were positioned 12 inches from the front outer-legs of the table.

**Boards and Measuring Key.** Expressions were displayed on boards made of a white foam poster board, cut into rectangles (45.7 cm x 30.5 cm) and supported by 30.5 cm easel backs. The boards angled slightly, so that the top was slightly further from the participant than the bottom.

A total of eight boards were made, one for each arithmetic expression. The boards were placed at distances both within and out of reach to the participant. Measured from the back of the chair, expressions were placed at four distances: 80cm, 40cm, 110cm, and 50cm.

**Questionnaires.** Participants completed the Abbreviated Math Anxiety Scale (Hopko et al., 2003) and WRAT-3 assessment (Roberston, 2010), as well as a questionnaire assessing each participant's particular math background and interests.

## Procedure

Participants sat in a chair facing the corner of the two tables. To familiarize the participant with the procedure, a warm up trial consisting single row of five dots was presented on the right-hand table at a distance of 80cm. Participants were informed that following the warm-up, the board would display arithmetic expressions instead of dots. Because we were interested in the potential long-term influence of operation ordering practice on distance perception, participants were not instructed in a particular solving method. In particular, participants were not reminded of the order of operations, but were simply asked to solve the problems as they usually would, and to do their best.

Participants were instructed to estimate the distance from their sternum to the center dot. Participants indicated their estimate by extending the tape measure along the left-hand table, with the blank side of a tape measure up. This method allowed the participant to have full control over the estimation process, while blinding them to the actual measurement. When providing their estimate, participants were not permitted to use the tape measure on the table displaying the board, nor were they allowed to reach out and touch the board.

During actual experimentation, the procedure followed in the same manner as the warm-up, substituting arithmetic expressions for the row of dots. Participants viewed four expression pairs displayed on boards set at one of four distances (80cm, 40cm, 110cm, 50cm) from the edge of the table closest to the participant. We repeated the procedure for each participant and with variance in the complexity of the math problems: four multiplication and four addition, with two easy and two complicated in each. Problems were paired, so that for each problem a participant solved while focusing on a multiplication sign, they later solved a problem identical except for the substitution of additions for multiplications. For example, if given the problem  $5+4 \times 3+7$ , we asked them to focus on the multiplication sign when giving their estimate. Immediately following their estimate, they proceeded to solve the expression aloud, step-by-step.

The order of distances was fixed, but the problem presentations were counterbalanced in a Latin Square design, leading to a total of eight conditions (see *Table 1*).

Table 2: Stimuli for Experiment 2 (Condition 1)

Expression	Center Operation	Distance (cm)	Difficulty
$3 \times 5 + 2 \times 7$	Add	80	Easy
$1/3 \times 4 + 2/3 \times 1/2$	Add	40	Difficult
$5 \times 8 + 2 \times 3$	Add	110	Easy
$1/4 \times 1/6 + 5 \times 2/3$	Add	50	Difficult
$3 + 5 \times 2 + 7$	Mult	80	Easy
$1/3 + 4 \times 2/3 + 1/2$	Mult	40	Difficult
$5 + 8 \times 2 + 3$	Mult	110	Easy
$1/4 + 1/6 \times 5 + 2/3$	Mult	50	Difficult

Each expression pair was set at the same distance. Thus, if  $5+4 \times 3+7$  was set at 50 cm, then  $5 \times 4+3 \times 7$  was also set at 50 cm. Between trials the participant was given a packet of mazes and instructed to complete as much of it as they could while the experimenter set up the next trial.

Following the distance perception session, the math anxiety level and abilities of each participant was assessed with a basic mathematics proficiency test, WRAT-3. Each participant was given 10 minutes to complete as much of the packet as they could, without returning to the problems they skipped. After the WRAT-3, participants completed the Abbreviated Math Anxiety scale.

## Results

Distance estimates (see *Table 3*) were subjected to an ANOVA using operation structure and problem difficulty, within-participants factors, and math anxiety and

precedence behavior as between-participant factors. Participant precedence behavior was coded by the experimenter as either the correct use of order of operations or the incorrect use. Participants who did not use the order of operations correctly tended to use other strategies, such as adding from left to right, or computing sums before products. It was typically difficult to discern what strategy a participant had used, and some participants tended to shift strategies over the course of a trial. To be clear: differences in operations based on precedence strategy are expected only among subjects who apply correct order of operations. There was no significant main effect of math anxiety on distance estimates ( $F(1,30)=.02, p \sim .9$ ) or in the interaction between math anxiety and problem difficulty on distance estimation ( $F(1, 30) = 1.10, p > .05$ ). There was, however, a significant interaction between the operation in focus and precedence behavior ( $F(1, 30)=5.0, p<0.05$ ), such that operations which were treated as high precedence yielded lower distance estimates. A follow-up analysis considering just participants who correctly used order of operations revealed a significant main effect of focal operation ( $F(1, 17) = 4.87, p < .05$ ). There was no significant interaction for who did not obey standard precedence rules; numerically, this group tended to estimate the plus signs as closer than the times signs ( $F(1, 12)=3.1, p \sim 0.11$ ).

Post-hoc analyses revealed a possible confound of the counterbalance condition, in that the condition in which the participant was randomly assigned seemed to influence whether or not they estimated the plus or times signs to be closer and the strategy used to solve the expressions. Specifically, those who received the conditions presenting the times sign as the operation in focus first tended to use order of operations when solving the expressions (87.5% correct precedence behavior), whereas those receiving the plus sign as the operation in focus tended not to (31% correct precedence). The effect of first operation on precedence behavior was significant by Fisher's exact test ( $p<0.01$ ); however, since this effect was not predicted ahead of time, it should be interpreted cautiously. To ensure that the main analyses were not affected by an overall linear trend in distance judgments across trials, the data were reanalyzed using problem order as a covariate; results were in all ways similar to those reported above.

Table 3: Mean (standard error) distance underestimated distance to central operations in Experiment 2.

Central operation	Precedence Behavior	
	Correct	Reversed or Left/Right
Plus	14.2 (1.7)	17.2 (1.4)
Times	16.8 (1.9)	15.6 (1.4)

## Discussion

Although our hypothesis that math anxiety would lead to overestimation of distances was not supported, our findings support the prediction that those who knew the order of operations would perceive the times sign to be closer. However, it is quite possible that null findings could be a result of such a small sample size. Taken together with the results from Experiment 1, high precedence operations afford immediate action and therefore, may appear to be closer. The effect of the experimental conditions suggest that attention may serve as a moderating variable between depth perception, anxiety, and the perceived efforts to enact an action.

## General Discussion

Two experiments verified and extended the basic findings of Landy & Linkenauger (2009), demonstrating a bidirectional relationship between perceived distance and effective arithmetic syntax. While prior results indicated a metaphorical relationship between distance and precedence, Experiment 2 here demonstrated that participants who correctly apply the order of operations also estimate the actual physical distance to high precedence sign as smaller than that to a low precedence sign. Furthermore, these are the first results to demonstrate that (simulated) physical distance affects the application of abstract formal operations.

Both of these phenomena are familiar in interactions with physical objects. Intentions and object affordances both impact perceived distance (Proffitt, 2006B). We know of no research directly exploring the impact of apparent distance on action selection, but it seems quite likely that actions with physical objects are selected in part on the basis of perceived proximity. In the current experiments, however, the relevant action is itself abstract, and the ease of adding and multiplying does not depend in any obvious way on physical proximity. The interpretation of interactions between apparent distance and abstract actions is thus less clear than with concrete objects. A dramatic reading might hold that explicit distance perception tracks the perceived difficulty of engaging in behavior—that is, that explicit perceptions of distance are fundamentally less concrete and more abstract than has previously been supposed. The fact that we did not find any sign of a relationship between math anxiety, problem difficulty, and perceived distance speaks against such a dramatic conclusion.

A more plausible interpretation is that abstract procedures, such as calculation are executed via systems normally devoted to perception and action (Landy & Goldstone, 2007, 2009; Goldstone, Landy, and Son, 2010; Landy, Allen, and Anderson, 2011). On this “Rigging Up Perceptual Systems” account, learning to engage in formal operations, such as operation ordering often involves adapting a pre-existing perceptual-motor system that already performs computations roughly appropriate to the to-be-learned content. Previously identified systems include the use of perceptual grouping and attention to perform

operation ordering (Landy & Goldstone, 2007, 2010; Goldstone et al 2010); it may be that some individuals implement operation ordering via distance perception mechanisms, learning to treat sub-expressions which should be ignored as farther away, and so leveraging powerful machinery that produces distance judgments to automatize routine computation.

It also seems possible that differences in perceived distance may simply be a result of focused attention: that is, it is possible that simply attending to an object increases its apparent proximity. Though we know of no direct demonstration of this possibility, attention is thought to affect other aspects of perception, such as contrast (Treue, 2004), apparent speed of motion (Turatto et al, 2007), and apparent size (Anton-erxleben & Treue, 2007; but see Schneider, 2008). Attentional focus may also influence perceived distance. This explanation provides a natural account for the influence of precedence judged distance and figure and ground perception in the face-vase illusion previously demonstrated by Landy & Linkenauger (2009). Furthermore, attention is thought to be necessary for action-specific effects on perceived distance (Cañal-Bruland et al., 2011) Finally, though it should be interpreted with caution, the unpredicted relationship between initial focal operation and both distance and precedence behavior is also compatible with an attention-based interpretation. It may be that asking people to attend to a particular sign influenced both ordering behavior and perceived depth.

## Conclusions

In our experiments, we did not find any effect of perceived difficulty on estimated distance, either when problem difficulty varied, nor based on personal skill or arithmetic self-efficacy. Of course, null results such as these must be interpreted with caution; nevertheless, there is little indication here of a very tight analogy between estimations of abstract difficulty and perceptions of physical distance.

On the other hand, we found substantial bidirectional influences between order of operations and perceived depth, suggesting that the relationship between action ordering and depth is not restricted to concrete behaviors, but is also involved in abstract actions as well.

## Acknowledgments

This research was partially funded by Department of Education, Institute of Education Sciences grant R305A110060, as well as an undergraduate research grant from the University of Richmond. Beth Crawford provided helpful comments on the design of Experiment 2, and Sally Linkenauger on the design of Experiment 1.

## Abstract

We examined the relationship between cognitive states and visually-induced self-motion perception, i.e. “vection” (latency, duration and magnitude). It is often anecdotally reported that time experienced in return travel (back to the start point) seems shorter than time spent in outward travel (travel to a new destination). Here, we report the first experimental results showing that return travel time is experienced as shorter than the actual time because of perceiving vection. Secondary, we explore how numbers are represented in depth in our mental space, we asked participants to sequentially speak random numbers while they observed forward/backward vection. We found that participants tended to generate larger numbers when they perceived backward self-motion. Finally, We found that all the measures of vection correlated negatively with the degree of narcissistic traits of participants.

**Keywords:** vection, time perception, mental number line, personality

## Introduction

Self-motion perception as determined by vision alone is called ‘vection’ (e.g. Fischer & Kornmüller, 1930). Stimulus attributes for effective vection induction have been extensively studied (Seno et al., 2009). Recently, the relationships between vection and cognition were examined. Vection and attention (Seno et al., 2011a), time perception (Seno et al., 20011b), cognitive bias (Palmisano & Chan,

2004), quantity perception (Seno et al., 2011c) and personality (Seno et al., 2011d) have been reported. In this article we introduce our three examples that vection alters cognitive states. Those examinations have not been conducted before. Our experiments were the first challenges of vection and multi dimensional human cognition.

## Time perception and vection

A number of factors have been known to modulate the subjective duration of the interval in time, e.g., attention to time passage (e.g. Zakay & Block, 1997), subjective event number in the stimulus presentation period (Poynter, 1989), whether the task is prospective or retrospective (e.g. Doob, 1971) and the boredom impatience and anticipation (Brown, 1985). Adding a dual task (in addition to the evaluation of the interval time) increases the errors and decreaseS the accuracy of evaluation (Brown, 1997 review). As a new factor of determining experienced time, we show that a return travel is perceived shorter in time than an outward travel. We succeeded in showing that vection strength modulate the shrinkage of the return travel. This was a very new finding.

## Method

We presented participants with virtual travel from Fukuoka, Japan, to a world-famous city, such as Paris, and examined subjective durations of stimulus movies, i.e. expanding-

optic-flow or dynamic-random-dot (DRD). We presented expanding flow during both the outward and return travels under the optic-flow condition. A round trip was assigned a cover story. Before the movie presentations, subjects understood that they would be asked to estimate the time durations of the stimulus presentation. We stated “Now we will go to Paris from Fukuoka” before the first stimulus presentation (outward trip). After the first stimulus presentation and before the second stimulus presentation, we stated “Now we will go back to Fukuoka from Paris” (return trip). Stimulus images were presented on a display with  $1,024 \times 768$  pixel resolution and at 75 Hz refresh rate. Each optic-flow display consisted of 16,000 randomly placed white dots on a black background. The dots were uniformly distributed within a simulated cube which subtended  $72$  (horizontal)  $\times$   $57$  (vertical) deg in visual angle. The stimuli were displayed on a 50-inch plasma display, with a viewing distance of 57 cm. The optic-flow simulated the forward or backward self-motion in constant-velocity (16 m/s). The DRD was refreshed at 75 Hz and the numbers of the dots were also 16,000. Twenty undergraduate students participated in each condition. The physical duration of stimulus presentations was 40 sec. Subjective durations were orally reported.

There was additionally the static-plane condition. A static random-dot plane was virtually placed 30 cm farther than the optic-flow plane (Figure 1). The farther dot plane effectively inhibited self-motion perception (e.g. Seno et al., 2010).

There were three stimulus conditions, optic flow, DRD and the static-plane conditions. The expected vection strengths were strong, medium and nothing for optic flow, static-plane and DRD conditions respectively. The destination of the trip was randomly chosen from ten very famous world cities (e.g. New York, Tokyo, etc.). The expected vection strengths for the three conditions were estimated from our previous study (Seno et al., 2010). Those subjective strengths were 60, 40, 0 for optic flow, Static plane, and DRD respectively (100 was very strong vection and 0 was no vection).

## Results and discussion

In the optic-flow condition, return travel was perceived as 5 sec shorter than the 40-sec physical presentation duration ( $Z=6.49$ ,  $p<0.01$ ). In the static-plane condition, the estimated duration in return travel was slightly longer than that; however, it was still shorter than 40 sec ( $Z=3.02$ ,  $p<0.05$ ). In the DRD condition, there was no shrinkage of the return travel.

We plotted the differences in subjective durations between outward and return-travel trials (Figure 2). Positive values indicated subjective time shortening in return travel for the round-trip conditions. Only in the optic flow and static-plane conditions, those values were significantly larger than 0 ( $z=11.97$ ,  $4.83$ , respectively,  $p<0.01$ ). That is, return travel was perceived as significantly shorter than outward travel in the two conditions.

Perceived time shrinkage was induced by perceiving vection. The degree of the shrinkage was correlated to the strength of vection. Miles et al. (2010) reported that, depending on the vection direction, daydreaming was oriented to the future or the past. Considered together with our results, vection seems to have some power to alter cognition.

Figure 1. A schematic illustration of the farther-plane condition.

Figure 2. The shrinkage of the return travel. Error bars indicate SEM.

## Mental number line and vection

Previous studies have revealed a close connection between the representation of numbers and space (see Hubbard et al 2005 for a review); numerical magnitudes are represented in a mental number line (MNL) in an ascending order from left to right (e.g. Dehane et al 1993) and from bottom to top (e.g. Schwarz and Keus 2004).

The representation of MNL is tightly linked with our body motion. For example, Loetscher et al (2008) asked participants to generate random numbers orally whilst turning their head, and found that participants generated ‘small’ numbers more frequently when they turn their head to the left than to the right. A correlation between the magnitude of generated numbers and the direction of saccades has also been reported (Loetscher et al 2010): participants made rightward saccades just before they generated the larger numbers while they made leftward saccades when generated the smaller numbers.

Previous studies have only examined the MNL on the 2D plane. The goal of this study was to explore space-number interaction in the front-rear direction by using induced vection. Specifically, we asked participants to complete the random number generation task whilst they perceived the forward/backward body motion induced by expanding/contracting optic flows. This challenge was quite new and there has never been such study.

## Method

In each trial, whilst observing the optic-flow, the participants had to report orally four different numbers. Instruction was given as follows: “Please speak four different numbers in the interval between 0 to 100 as random as possible.” To make sure of the occurrence of vection, there was a 10 s interval between stimulus onset and the start of the task (for the delay of vection induction). Ten participants generated 8 numbers (4 x 2 trials) and the other ten participants generated 16 numbers (4 x 4 trials) for each direction of the optic-flow. The expanding and contracting trials were randomized. Twenty participants observed optic-flows in a dark chamber.

The perception of optic flow-induced vection was verified in a separate session after conducting the number generation session, when the magnitude and duration of vection with the same visual stimuli was measured.

## Results and discussion

The average of the generated numbers was significantly larger with the contracting motion than with the expanding motion (two-tailed paired t-test:  $t_{19} = 2.83$ ,  $p < .05$ ) (Figure 3). We found no bias such that observers generated numbers in an ascending or a descending sequence. The results showed that the sensation of self-motion could bias the magnitude of generated numbers, suggesting that, together with the previous results (Loetscher, et al. 2008, 2010), the representation of numerical magnitudes is tightly linked with our body motion. The present results suggest that the smaller numbers are represented in a front space while the larger numbers are represented in a rear space.

Figure 3. The average of generated numbers. Error bars indicate SEM.

## Personality

In our previous studies, we noticed that there were considerable individual differences between vection latency, duration and magnitude. Moreover, these individual differences appeared to be consistently exhibited, regardless of the stimulus conditions, i.e. an observer who perceived longer and stronger vection in one experiment also perceived longer and stronger vection in other vection experiments. These observations suggest that vection correlates with long-lasting characteristics of the participants. It has been reported that some cognitive abilities correlate with properties of personality (DeYong et al., 2005). For example, the performance of mental rotation (Ozer, 1987) or the magnitude of the attentional blink (McLean & Arnell, 2010) correlated with personality. A positive affectation influences performance in a variety of cognitive tasks (Ashby et al., 1999). The ‘Big Five’ factors of personality (openness, conscientiousness, extraversion, agreeableness, neuroticism) have also been found useful in predicting some everyday behaviors (Paunonen and Ashton, 2001). Therefore we thought that vection might also correlate with the personality traits of participants. We believe that the personality is one important aspect of human cognition. Thus this examination was one new challenge for vection and cognition.

## Method

We used an optic flow of expansion as vection stimulus. The duration of the stimulus was fixed at 40 seconds. Thirty adult volunteers participated in the experiment. Eight trials were conducted and the observers were asked to press a button when they perceived self-motion. At the end of each trial, the observers were also instructed to rate the subjective strength of vection using a magnitude estimation on a scale from 0 (no vection) to 100 (very strong vection).

After the vection task, the observers completed three questionnaires. The first included scales of public and private self-consciousness, which were Japanese versions of Fenigstein’s original index (Sugawara, 1984; Fenigstein et al., 1975). The second was the Narcissistic Personality Inventory Short Version (NPI-S; Oshio, 1999), based on the Narcissistic Personality Inventory developed by Raskin and Hall (1979). The third was related to the Big Five personality factor scales (Japanese version by Saito et al., 2001).

## Results and discussion

The results of the vection study were consistent with those found in our previous studies (the average vection latency, duration and magnitude were 12.25 seconds, 21.98 seconds, and 38.74, respectively), confirming the validity of the vection measures. Vection latency and total-NPI-S score were positively correlated ( $r^2 = 0.47$ ,  $p < 0.0001$ ), whereas duration or magnitude and total-NPI-S score were negatively correlated ( $r^2 = 0.28$ ,  $p < 0.003$ ;  $r^2 =$

0.19,  $p < 0.02$ , respectively) (Figure 4). No other comparisons between the three vection measures and personality scale scores showed any significant correlations.

We found that the more narcissistic the observer was, the weaker the perception of vection was.

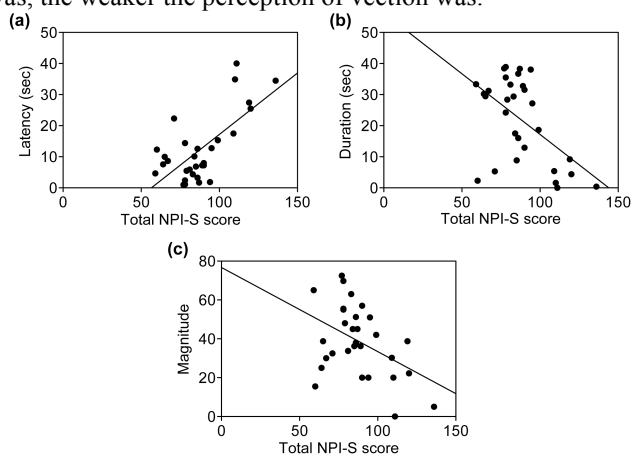

Figure 4. Correlations between vection measures (a: latency; b: duration; c: magnitude) and total-NPI-S score.

## Conclusion

We here showed three examples that vection alters our cognitive states. They were all new findings. Vection induced shrinkage of time of the return travel. Vection revealed our mental number line in depth. Vection and personality were correlated. Further examinations of the relationship between vection and cognitive states should be done in the future.

## Abstract

For many years, research has been done to find the best way to make decisions. Dijksterhuis and Nordgren (2006) formulated the Unconscious Thought Theory (UTT), stating that when making complex decisions it is better not to think consciously, but to direct your attention elsewhere, letting the unconscious make the decision. However, a wealth of research has found evidence against the predictions of UTT. Thorsteinson and Withrow (2009) found that participants, who were allowed to take notes during the information intake stage, made better decisions thinking consciously. The current study is a replication of Thorsteinson and Withrow (2009), being a four conditions design (immediate decision, unconscious thought, conscious thought or conscious thought with notes) with the addition of intelligence as a variable. The conclusion of Thorsteinson and Withrow (2009) is supported: The best complex decisions are made when participants take notes and use them while thinking consciously. Moreover, it is shown that intelligence is positively correlated with better decisions.

## Introduction

When you buy a new house or car, you face a complex decision with many choice options that have different advantages and disadvantages. There are several ways to make this decision. You could try to list up all the different attributes of all the choice options, and think deeply about which option best suits your needs. Another strategy would be to make sure you are well informed about the different options, but not to decide immediately. After a good night of sleep, a gut feeling will arise, a preference for one of the options, even though you don't know where it came from. These are two completely different ways of making a complex decision, and throughout the years, there has been a lot of discussion about the intriguing question which of these strategies results in the best decisions.

For a long time, decision-making has been seen as a matter of rationality, objectivity and reflection. According to this view, a good decision can be made by breaking down the decision into small amounts of information, which have to be evaluated separately (e.g., Edwards, 1961; Dawes & Corrigan, 1974).

Later, this view has been challenged. Dijksterhuis, Bos, Nordgren, and van Baaren (2006) formulated the *deliberation-without-attention* hypothesis, stating there is a trade-off between the complexity of a decision and the usefulness of conscious thought when making the decision. To make an easy decision, it is better to think consciously, whereas unconscious thought should be used to solve more complex, broader decision problems. Unconsciousness is

believed to have an equal performance, no matter the difficulty level of the choice. Consciousness, in contrast, is especially good at making easy choices, even better than unconsciousness. But as decisions get more complex, consciousness has more problems with decision making, thereby performing worse than unconsciousness (Dijksterhuis et al., 2006). The deliberation-without-attention hypothesis is drawn from the Unconscious Thought Theory (UTT; Dijksterhuis & Nordgren, 2006), which explains the different characteristics of conscious and unconscious thought.

UTT and the deliberation-without-attention effect seemed to explain findings in earlier research (e.g., Wilson & Schooler, 1991; Wilson et al., 1993; Halberstadt & Levine, 1999). Research by other authors, however, led to conclusions that cannot be explained by UTT. In Experiment 1 of Thorsteinson and Withrow (2009), participants had to recall as many attributes as possible, before or after judging the different choice options. Only when judgement preceded recall, results provided evidence for the deliberation-without-attention hypothesis. The authors argued, however, that by recalling attributes, the participants in the unconscious-thought condition engaged in a form of conscious thought. It was also argued that the weighting principle of UTT is based on a weighted-additive model (WADD), but that a TALLY-model is used in research by Dijksterhuis (2004) and Dijksterhuis et al. (2006) to measure the quality of the choice (Newell et al., 2009). A weighted-additive model calculates the quality of a choice by the weight of every attribute, for example, if a cup holder is less important in a car than a good mileage, the cup holder should not get as much weight in the calculation of the quality of the cars. A TALLY-model calculates the options by simply adding the number of positive attributes. A cup holder thus has as much influence on the car's score as a good mileage.

In order to clarify the contradicting findings in the literature, a meta-analysis was conducted by Acker (2008), which showed a large heterogeneity between different studies. It revealed a small but unconvincing advantage in favour of unconscious thought. Since different studies led to other conclusions, more research is needed to clarify under which conditions unconscious thought can be useful.

Previous research showed that unconscious thought does not necessarily perform better under certain circumstances. One specific condition under which unconscious thought seems to lose its advantages is when participants are not obligated to rely on their memory when

making a decision. Some research already exists on this topic, but the current study will try to further elaborate some missing parts. Of special interest for the current study, is Experiment 2 of Thorsteinson and Withrow (2009). In this experiment, participants were given the opportunity to overcome their memory limitations, thereby changing the outcomes of the deliberation-without-attention effect. Laboratory studies by Dijksterhuis and colleagues (Dijksterhuis, 2004; Dijksterhuis et al., 2006) follow the same paradigm. Participants are given information about different choice options (e.g., cars, apartments or roommates). After having consciously read all the attributes of the different choice options, they have to make a decision immediately (immediate-condition), after a few minutes of conscious thought (conscious-thought condition) or after a few minutes of distraction (unconscious-thought condition). Thorsteinson and Withrow (2009) included a fourth condition in this paradigm, the conscious-thought-with-notes condition. Participants in this condition were allowed to take notes of the attributes during the presentation period, and use these notes while thinking consciously about their decision. Memory limitations would not influence the quality of the choices of these participants. Participants in the conscious-thought-with-notes condition turned out to make better decisions than participants in the other conditions. The mean unconscious score did not differ significantly from the mean score in the conscious-thought condition without notes. This study thus was unable to replicate the findings of Dijksterhuis et al. (2006), but showed that, when overcoming memory limitations, conscious thought seems to be beneficial for complex decisions. Newell et al. (2009) also included a conscious-thought condition with information in their second experiment. In this condition, participants were provided with an information sheet containing all the attributes, while thinking consciously. Participants in this condition made better choices, but the difference was only significant compared with the immediate condition, not with the unconscious-thought condition. Rey et al. (2009) found that participants in their conscious-thought condition, who also had access to the information while thinking consciously, performed worse. The effect of using a memory aid does not seem clear yet. Too little research has been done to date to draw a clear conclusion. The current study aims to provide a valuable addition on this topic.

Also important is the method Thorsteinson and Withrow (2009) used to measure the quality of the choice. Participants were asked to rate the attributes on importance for them. The description of the four choice options, in this study: non-existing cars (materials from Dijksterhuis et al., 2006), is formulated in bipolar attributes, for example, a car does or does not have a cup holder. Therefore, a score for each car can be calculated for each participant by multiplying the importance score of an attribute with either minus one (if the attribute is negative for this car) or one (if the attribute is positive for this car). As a dependent measure, Thorsteinson and Withrow (2009) calculated the difference between the score of the car with the highest score and the score of the chosen car. A participant thus had a score of zero if the chosen car was the best possible car

for this participant, and higher than zero if he/she chose another car. This way, a WADD-model was used to measure the quality of a choice. The current research will include both a TALLY and two WADD calculations (a dichotomous WADD measurement and a continuous variant), in order to find the model that represents best human decision-making.

Despite the diversity of phenomena related to IQ, few have attempted to understand – or even describe – its influences on judgment and decision making (Frederick, 2005). Studies on time preference, risk preference, probability weighting, ambiguity aversion, endowment effects, anchoring, and other widely researched topics rarely make any reference to the possible effects of cognitive abilities (or cognitive *traits*). The majority of studies approach the deliberation-without-attention effect as a universal effect, being applicable to all participants. However, it could be possible that one mode of thought would be more beneficial for some participants, but not necessarily for others. Therefore, individual differences in intelligence will be studied in the current research. The short version of Raven's Advanced Progressive Matrices (Bors & Stokes, 1998) will be used to measure intelligence. To our knowing, no research on the influence of intelligence on the deliberation-without-attention effect has been done to date. However, it might influence the decision quality. A higher intelligence level could be an advantage when processing the information. Furthermore, when using conscious thought to make a decision, the quality of the analysis of the information could be influenced by intelligence.

## Experiment

### Method

#### Design and Participants

A total of 341 participants were taken over different educational levels. Participants were recruited from university students and students in secondary education. The sample thus contained participants engaging in academic education ( $n = 213$ ), general secondary education ( $n = 37$ ), technical secondary education ( $n = 41$ ), and vocational secondary education ( $n = 24$ ). University students participated in exchange for course credits, secondary educational students did so voluntarily. Ages of the participants ranged from 16 to 30, of which 99.1% was 24 or younger. Participants were randomly assigned to one of the four conditions (immediate, unconscious-thought, conscious-thought, and conscious-thought-with-notes condition).

#### Procedure and Material

As in most research on UTT, the paradigm of Dijksterhuis (2004) was used. All participants were presented 48 attributes from four different, nonexistent cars (12 attributes per car). These stimulus materials were taken from Dijksterhuis et al. (2006), the same as used in Thorsteinson and Withrows (2009) second experiment. Each attribute was formulated either positive or negative. All cars were described on the same 12 features. The Hatsdun had 75% positive attributes, whereas the Nabusi was characterized by only 25% positive features. Two more

neutral cars were included, with the Kaiwa having 58% and the Dasuka 50% positive attributes.

Because participants were also recruited under the national legal age for a driving licence, it could possibly be hard for them to imagine buying a car. To make sure that these younger participants would perceive the materials the way intended by the researchers, a pre-test was conducted with a small sample of secondary education students, none of whom participated in the real experiment ( $n = 13$ ). The materials used by Thorsteinson and Withrow (2009) in their first experiment, which contained attributes from apartments, were tested at the same time, to find out which materials suited best the needs of participants their age. Half the sample were given the attributes in a positive formulation (e.g., "The car has good mileage."), and were asked to rate the importance of the attributes. The other half received the same attributes, but negatively formulated (e.g., "The car has poor mileage.") and were asked to rate how bad they felt about the car not having the feature. A mean score for each choice option was calculated, by multiplying the mean score of each attribute by either minus one (if the choice option did not have the feature) or one (if the choice option did have the feature), and summing these. The results showed that, for both sets of materials, features that were intended to be positive, were perceived as positive, and those intended to be negative, were perceived as negative. The choice options were ranked in the same order as intended. Since both sets were suitable, the car-materials were used to make comparison with Thorsteinson and Withrows (2009) second experiment easier.

In the real experiment, participants in the conscious-thought-with-notes condition were instructed that they were allowed to write down whatever they wanted during the presentation of the information, whereas participants in the other conditions were just instructed to pay attention to the attributes presented. They all knew they would have to make a decision on which car they preferred, resulting in impression forming (Lassiter et al., 2009). The 48 attributes were presented in a random order, for eight seconds each, using E-prime software (Psychological Software Tools, Pittsburgh, PA).

After the presentation of the information, participants in the conscious-thought conditions had four minutes to think carefully about the different cars. After four minutes, they had to choose the car they preferred. Then they were asked to rate the 12 different attributes on importance, on a scale from one, meaning "no importance at all", to seven, meaning "very important". This made it possible to calculate the subjective preferences of each participant. In the unconscious-thought condition, participants were distracted for four minutes by solving anagrams, before they had to make their decision and rate the attributes. In the immediate condition, participants had to choose their preferred car immediately after the presentation of the information, followed by the rating of the attributes, and were then instructed to solve the anagrams as a filler task in order to obtain the same the experiment duration in all conditions.

After these tasks, all participants were asked to fill in the short version of Raven's Advanced Progressive Matrices (Bors & Stokes, 1998). During the last decade, this has been one of the most widely used instruments by researchers interested in participants' inductive or analytic reasoning capacities or fluid intelligence (Cattell, 1963). Raven's Advanced Progressive Matrices (Raven, Court, & Raven, 1988) or APM is a version of these matrices intended for use with people above average aptitude and designed to reliably differentiate among those in the top 25% of the population (Bors, & Stokes, 1998). In the present study a short version of the APM (Bors, & Stokes, 1998) has been used. It is a selection of 14 items with increasing difficulty drawn from Set 2 of the original APM (item 3, 10, 12, 15, 16, 18, 21, 22, 28, 30, 31 and 34). For all 14 items, participants had to indicate which was the missing segment required to complete a 3x3 matrix, which takes about 20 minutes. All parts of the experiment were presented in Dutch.

## Results

First, the proportions of participants choosing the best car according to a TALLY-model, were compared between the different conditions, following Dijksterhuis (e.g., Experiment 2 in Dijksterhuis, 2004). As shown in Figure 1, participants in the conscious-thought-with-notes condition performed best, with a proportion of 0.578 choosing the Hatsdun, which had the most positive features. Participants in the conscious-thought condition, who did not take notes, performed only slightly worse (.54). Participants in the unconscious-thought condition made the worse choices, with a proportion of only .32 choosing the Hatsdun. Those who couldn't engage in any form of thought, in the immediate condition, scored in between the conscious and unconscious-thought conditions, with a proportion of .48 choosing the objectively best car. An ANOVA showed that the main effect was statistically significant:  $F_{(3, 337)} = 4.64$ ,  $p < .01$ ,  $MSE = .24$ . Tukey contrasts showed that the differences between both conscious-thought conditions and the unconscious-thought condition were significant, with  $p < .01$  for the conscious-thought-with-notes condition and  $p < .01$  for the conscious-thought condition.

Since UTT is based on a WADD-model, and the proportion of participants choosing the Hatsdun is a TALLY measurement, the best weighted subjective choice options were calculated. For each participant, a unique rating for each car was calculated according to a WADD-model, by summing the importance ratings of each attribute, with the ratings of attributes that the particular car did not have, being counted negative.

It turned out that the Hatsdun was, subjectively, not the best car for each participant. For 23.2% of the participants, another car than the Hatsdun had a higher or equal subjective score, so not choosing the Hatsdun was not necessarily a bad decision for them. Therefore, the proportions of participants choosing their subjectively highest rated car were compared between the four conditions, making it a dichotomous WADD measure (see Figure 2).

Figure 1. Proportion of participants choosing the best car according to a TALLY-model (the Hatsdun) under different conditions.

Figure 2. Proportion of participants choosing their best option according to a dichotomous WADD-model under different conditions.

In all conditions, the proportions of participants choosing their subjectively best car were higher than the proportions of those choosing the Hatsdun, indicating that participants in all conditions followed a weighted decision model. The pattern of differences between the conditions changed, but the ranking remained the same. Unconscious thinkers scored relatively better with this weighted measurement, with a proportion of 0.553 choosing their subjectively best car. However they still performed worse than participants in all other conditions. Participants in the immediate condition chose their subjectively best choice option with a proportion of .62, in the conscious-thought condition with a proportion of .66 and in the conscious-thought-with-notes condition with a proportion of .76. An ANOVA revealed that this effect was significant,  $F_{(3, 337)} = 2.83$ ,  $p < .01$ ,  $MSE = .23$ . Post-hoc Tukey contrast showed that participants in the conscious-thought-with-notes condition made significantly better decisions than those in the unconscious-thought condition,  $p < .01$ .

It could be argued that not choosing the car that suits one's subjective needs best, does not mean the choice was necessarily a bad one, since for some participants the subjective scores of some choice options didn't differ

much. For example, one participant had chosen the Kaiwa, with a subjective score of 22, but the best option for this person would have been the Hatsdun, with a score of 24. This choice was not as bad as the choice of another participant who had also chosen the Kaiwa, with a subjective score of -6 as opposed to his best option, the Hatsdun, with a subjective score of 18. Therefore, to measure the real quality of a participant's choice, the continuous WADD calculation of Thorsteinson and Withrow (2009) was used. For each participant, the subjective score of the chosen car was subtracted from score of the car with the highest subjective score. Participants that chose the car that suited them best thus had a difference score of zero. The higher the difference score, the worse the choice made by the participant. This continuous WADD measurement seemed to fit participants' decision patterns best, because 14.2% of those who did not choose their best option according to the dichotomous WADD-model, had a difference score of only two. With difference scores ranging up to 68 in the total population, these choices were not necessarily bad ones. When using the difference score as the dependent variable, the pattern remained the same but the relative difference between the unconscious-thought and the conscious-thought-with-notes condition increased. Participants engaging in unconscious thought had a mean difference score of 6.87, thereby performing only slightly worse than participants in the immediate (6.60) and conscious-thought condition (5.10), but remarkably worse than those in the conscious-thought-with-notes condition, with a mean difference score of only 2.467 (see Figure 3). An ANOVA showed that this effect was significant,  $F_{(3, 327)} = 2.99$ ,  $p < .01$ ,  $MSE = 122.29$ . Post-hoc Tukey contrasts indicated that the difference between the conscious-thought-with-notes condition and the unconscious-thought condition was significant,  $p < .01$ . The mean difference score of the conscious-thought-with-notes condition was also marginally significantly lower than the mean score of the immediate condition,  $p < .05$ .

Finally, intelligence seems to influence decision quality. In the total population<sup>1</sup>, a positive correlation<sup>2</sup> was found between the scores on the short version of Raven's Advanced Progressive Matrices and the proportion of participants making the best decision according to a dichotomous WADD model (.17). A negative correlation with the difference scores (-.10) also provided evidence that a higher intelligence level leads to better decisions. Within the different conditions, no correlations with the difference scores were found, but the dichotomous WADD scores correlated positively with the intelligence measure in the immediate (.21) and unconscious-thought conditions (.27). In the immediate condition, a correlation with the TALLY measurement (.20) was found.

<sup>1</sup> To make sure the different levels of intelligence were equally spread over the different conditions, t-tests were conducted. No significant differences were found.

<sup>2</sup> All reported correlations are significant at the .05 level except for the correlation with the dichotomous WADD model in the total population, which is significant at the .01 level.

Figure 3. Means of difference scores (continuous WADD-model) under different conditions.

## Discussion

The results of this experiment did not support the predictions of UTT. Using three different methods to measure decision quality, including the measurement used by Dijksterhuis (2004), no evidence for a beneficial effect of unconscious thought was found. In contrary, participants in the unconscious-thought condition performed worst of all participants, significantly worse than participants in the conscious-thought-with-notes condition. It thus seems that overcoming memory limitations is enough to make conscious thought a better decision strategy. But even without notes, participants engaging in conscious thought outperformed those engaging in unconscious thought. Even though this difference was only significant when a TALLY-model was used to measure the decision quality, the results of the other measurement methods still show the opposite pattern as predicted by UTT. The results of Thorsteinson and Withrow (2009) were confirmed.

Another important finding is that participants seemed to follow a WADD-model to make their decisions. In all conditions participants chose the car that was best for them, as calculated with a weighted additive model, more often than the car that was best according to a TALLY-model. A continuous WADD-model measured decision quality even better. This finding adds up to the findings of other research in support of using a WADD-model to measure decision quality (Newell et al., 2009; Thorsteinson & Withrow, 2009). Also from a theoretical point of view, a WADD-model should be used, since it reflects the weighting principle of UTT better. However, even when using this weighted measure, conscious thought seems to outperform unconscious thought when notes can be taken. These participants had an advantage since they were able to structure the information and select what to write down, writing only down what they consider important for their decision. These advantages made weighting easier. Under these circumstances, it thus seems that conscious thought is beneficial.

Individual differences also seemed to influence decision quality, but not under all circumstances. For the

overall population, intelligence seemed beneficial for the decision quality, but in the conscious thought conditions, no correlation could be found. This might be due to the overall better decisions made in these conditions.

# When Choice Effects Compete: An Account by Extended EBA Model

Kenpei SHIINA (shiina@waseda.jp)

Department of Educational Psychology, Waseda University, Tokyo, Japan

## Abstract

A modified version of EBA is proposed to account for choice set effects (similarity, attraction, and compromise) and their interactions. The new model has ingredients of search-for-dominance-structure theory and counter race model, highlighting conflict resolution and deliberation in decision making. Simulation results show that the model can reproduce the choice set effects and predict the interactions between them.

**Keywords:** EBA; Choice Set Effects; Dominance Structuring ; Race Model.

## The EBA Model Revisited

The elimination by aspects model (EBA, Tversky, 1972a, b) is a classical and well-known model, which remains attractive because it was one of early models that provided a clear processing assumption for choices with mathematical rigor. EBA model asserts that an aspect is probabilistically selected and options that do not have this aspect are discarded. (In this paper, attribute, aspect, and feature are used interchangeably). Another aspect is then selected and options that do not have the second aspect are discarded. Proceeding in this way, the EBA process terminates when only one option remains. Although EBA is a simple model that does capture an important facet of decision making, there are many empirical effects and theoretical notions that the model cannot explain. This paper describes an updated version of EBA model that can account for choice set effects (e.g., similarity, attraction, and compromise effects) and their interactions.

The paper consists of four parts: The first section briefly reviews properties of EBA in view of theories and findings after its proposal in 1972. In the second section, a modified EBA called REGAL model is proposed (Shiina, 1994, for an earlier version): the model incorporates the ideas of dominance structuring and race model. In the third section, a simulation study is presented that shows how the new model explains choice set effects and their interactions by producing probability topographies. Finally, implications for further research on choice and decision making are addressed.

## Original EBA and its Properties

We use the following symbols and notations (Figure 1a).

$T = \{X, Y, Z, \dots\}$ : The finite total set of choice alternatives.

$\Omega = \{\alpha, \beta, \gamma, \rho, \dots\}$ : The finite total set of features (aspects).

$x', y', z', \dots \subseteq \Omega$ : Subsets of  $\Omega$  representing  $X, Y, Z, \dots$

For example, if  $X$  has features,  $\alpha, \rho, \omega$  and  $\theta$ , then

$x' = \{\alpha, \rho, \omega, \theta\}$ . It is assumed that  $\Omega = \bigcup_{x' \in T} x'$ .

Figure 1a

Figure 1b

## Common Aspects

Aspects that are common to all the alternatives ( $\omega$  in Figure 1a) should be ignored in EBA whereas there is evidence that common aspects play an important role both in decisions and choice satisfaction (Chernev, 1997). It seems very unnatural, moreover, that we should intentionally ignore the important features, common or not, that come to mind. If we consider a version of EBA that permits common aspect selection (Common aspect EBA or CEBA), it can be proved that CEBA does not change choice probabilities and can produce decision time predictions. Suppose that  $T = \{X, Y, Z\}$ ,  $x' = \{\alpha, \rho, \theta, \omega\}$ ,  $y' = \{\beta, \rho, \sigma, \omega\}$ , and  $z' = \{\gamma, \sigma, \theta, \omega\}$  (Figure 1a) with the understanding that  $\alpha = u(\alpha)$  etc., where  $u()$  is a utility (value) function. In binary case :  $T = \{X, Y\}$ , we have

$$P(X \leftarrow \{X, Y\}) = (\alpha + \theta) / (\alpha + \theta + \beta + \sigma)$$

$$P(X \leftarrow \{X, Y\}) = (\alpha + \theta) / L + (\rho + \omega) / L \times P(X \leftarrow \{X, Y\})^{CEBA},$$

$$\text{where } L = \alpha + \theta + \beta + \sigma + \rho + \omega$$

Solving the second expression for  $P(x \leftarrow \{x, y\})^{CEBA}$ , we have

$$P(X \leftarrow \{X, Y\})^{CEBA} = \frac{(\alpha + \theta) / L}{1 - (\rho + \omega) / L} = \frac{(\alpha + \theta) / L}{\{L - (\rho + \omega)\} / L}$$

$$= (\alpha + \theta) / (\alpha + \theta + \beta + \sigma) = P(X \leftarrow \{X, Y\})^{EBA}$$

This equivalence also holds true for trinary or more numerous choices and thus Tversky's exclusion of common features is well grounded. For example, in trinary case :

$$T = \{X, Y, Z\},$$

$$P(X \leftarrow \{X, Y, Z\})^{CEBA} = P(X \leftarrow T)^{CEBA} =$$

$$1 / K \times \{\alpha + \rho P(X \leftarrow \{X, Y\}) + \theta P(X \leftarrow \{X, Z\}) + \omega P(X \leftarrow T)^{CEBA}\}$$

$$= \frac{\alpha}{K} + \frac{\rho}{K} \left\{ \frac{\alpha + \theta}{\alpha + \theta + \beta + \sigma} \right\} + \frac{\theta}{K} \left\{ \frac{\alpha + \rho}{\alpha + \rho + \gamma + \sigma} \right\} + \frac{\omega}{K} P(X \leftarrow T)^{CEBA}$$

where  $K = \alpha + \beta + \gamma + \rho + \sigma + \theta + \omega$ . This expression is identical to EBA if common feature  $\omega$  is ignored. Setting

$$L = \alpha + \rho(\alpha + \theta) / (\alpha + \theta + \beta + \sigma) + \theta(\alpha + \rho) / (\alpha + \rho + \gamma + \sigma)$$

we can derive a simple recursive formula:

$$P(X \leftarrow T)^{CEBA} = L / K + \omega / K \cdot P(X \leftarrow T)^{CEBA}$$

$$= L/K + \omega/K \left[ L/K + \omega/K \cdot P(X \leftarrow T)^{CEBA} \right] = \dots$$

$$= \frac{L}{K} + \frac{L}{K} \frac{\omega}{K} + \frac{L}{K} \left( \frac{\omega}{K} \right)^2 + \frac{L}{K} \left( \frac{\omega}{K} \right)^3 + \dots + \left( \frac{\omega}{K} \right)^m P(X \leftarrow T)^{CEBA}$$

Therefore when  $m \rightarrow \infty$ , we can derive an expression that is identical to the trinary EBA, because

$$P(X \leftarrow T)^{CEBA} = \frac{L}{K} \frac{1}{1 - \omega/K} = \frac{L}{K - \omega}$$

$$= \frac{\alpha + \rho(\alpha + \theta) / (\alpha + \theta + \beta + \sigma) + \theta(\alpha + \rho) / (\alpha + \rho + \gamma + \sigma)}{\alpha + \beta + \gamma + \rho + \sigma + \theta} = P(X \leftarrow T)^{EBA}$$

The generalization to  $n$ -option situation is straightforward, which gives reason for the idea that common features are processed but are indifferent to the final choice, and how the CEAB interpretation produces decision time predictions, because this interpretation yields a geometric distribution which permits rough estimates of decision times.

### Conjunction of Features and Dominance

It appears that EBA uses attributes one at a time. A careful reading of the original paper reveals, however, that an aspect can be an aggregate or conjunction of aspects. The aspect  $\alpha$  in Figure 1a, for example, may itself be a set of sub-aspects  $\{\alpha_1, \alpha_2, \alpha_3\}$  as in Figure 1b. In Figure 1, the choice of  $\alpha$  automatically leads to the choice of X. This paper interprets this property as “X was chosen because X dominated other options on  $\alpha$ .” If  $\alpha = \{\alpha_1, \alpha_2, \alpha_3\}$ , the interpretation will be “X was chosen because X dominated the other options on  $\{\alpha_1, \alpha_2, \alpha_3\}$ ”.

Dominance or dominance structuring is another key concept in the present paper. According to Montgomery & Willen (1999, p.148), “the decision maker attempts to find a dominance structure, that is, a cognitive structure in which the to-be-chosen alternative dominates other alternatives on relevant attributes.” It seems natural and promising to interpret EBA within the framework of search for dominance structuring (SDS) theory (Montgomery, 1989; Montgomery & Willen, 1999).

Because SDS model asserts that dominance should be established on a *bundle* of relevant attributes, a to-be-chosen alternative should be dominant on the conjunction of relevant attributes. A comparison of EBA and SDS in this respect gives a novel perspective; EBA is a very limited SDS in the sense that EBA process is a type of dominance structuring based upon a single attribute or a bundle of unique attributes. The key ideas linking EBA and SDS models are that dominance structuring is performed on a *conjunction* of attributes and the conjunctive set is *sampled* from the total set of attributes and thus changes over time. The conjunction of attributes is called an *evaluation set* or an *aspect lineup* in the model to be presented. An evaluation set is a set of attributes, so it is totally different from the reconsideration set, which is a set of alternatives.

### Reconsideration, Deliberation, and Deferral

Decision deferral and deliberation are two sides of the same coin because, in both cases, the decision maker cannot resolve decisional conflict at hand and thus deliberation evolves over time. Whereas it is often said that there are no widely accepted definition of conflict (Tversky & Shafir,

1992), we adopt the simple definition of Coombs and Avrunin (1988, p.222) that conflict arises in “a situation in which a choice must be made in the absence of dominance”.

It is often argued that EBA is suitable for relatively easy everyday choices, but may lead to less than optimal decisions. Janis and Mann (1977, p.32) pointed out, for example, that the decision maker may run out of relevant aspects and/or alternatives before reaching a decision, or may end up taking an alternative that is inferior to those eliminated.

If a pure EBA processing is used, it is almost inevitable that we may arrive at a much inferior choice with some probability. In that case, it will be very hard to justify both the final outcome and the choice process leaving a strong feeling of regret. We may start over, reconsidering discarded attributes and alternatives, whereas the original EBA does not have the mechanism to allow for such reprocessing. It is obvious that we should deliberate when the decision problem at hand is very important (buying expensive items, choosing a spouse or a job, etc.). Deliberation is a time-developing process and can continue for months or even years, during which time we think about the choice repeatedly. In this regard, an EBA model reinforced by SDS seems very appealing, because deliberation and justification are the key concepts of the SDS theory. Further, the combination is consistent with the current consensus that preferences are actively constructed, not merely revealed (Bettman, Luce, & Payne, 1998).

### Conflict Resolution and Counter Model

Tversky himself later maintained that decision making is a type of conflict resolution and that justification for the decision is necessary (Simonson, 1989; Simonson & Tversky, 1992; Tversky & Shafir, 1992; Shafir, Simonson, & Tversky, 1993). Dominance structuring is one method of conflict resolution and, if successful, it makes the choice self-evident (Montgomery & Willen, 1999, p.148). Although there are easy decisions that can be made almost automatically, decision makers facing an important decision should repeat consideration. Therefore, a counter or race model (Smith & Van Zandt, 2000) may be hypothesized in which the confidence for each alternative is accumulated during reconsideration, as the decision problem is addressed from many perspectives over time. This reconsideration process, possibly with repeated generation of evaluation set by attribute sampling, would be necessary to make the decision satisfactory or satisficing.

### REGAL Model

The REGAL (REpeated-Generation of Aspect Lineup) model integrates concepts from EBA, SDS, and the race (counter) models and tries to extend EBA in the following ways. First, reconsideration of aspects and alternatives is allowed, as this is an undeniable aspect of real-world decision-making. Second, REGAL permits the generation of conjunctive aspects, because a decision maker often has a bundle of minimum but unstable requirements that can be represented by a fluctuating conjunction of aspects. Third,

REGAL does not ignore aspects that are common to the alternatives, because there is evidence that common aspects do affect choice by enhancing the satisfaction. Finally, the concepts of counter and criterion (threshold) are adopted from race model to allow for decision time predictions.

In short, our revised EBA incorporates a) *reconsideration and deliberation processes*, b) a more *flexible aspect selection* that permits conjunctions, c) the processing of *common features*, and d) decision time generation processes.

### The Flow of the REGAL Model

The processing flow of the model is as follows (see also Figure 2 and Appendix):

(1) Let  $T$  be the set of alternatives and  $\Omega$  be the set of attributes used to represent the alternatives. The set  $x' \subseteq \Omega$  is the feature representation of Alternative  $X$ .

(2) A decision maker probabilistically samples a set of attributes  $\Psi$  from  $\Omega$ , called an *evaluation set* or an *aspect lineup*. The evaluation set is repeatedly regenerated during each cycle of REGAL process as shown schematically by the loop from (6) back to (2) in Figure 2. The reconsideration processes are represented in the loop.

(3) The degree of satisfaction for each alternative is evaluated on the *current evaluation set* determined in (2). The degree of satisfaction  $0 \leq S_\Psi(x) \leq 1$  is defined as

$S_\Psi(x) = \text{Goodness of Option } X \times \text{Structural dominance of } X \text{ over the other alternatives on evaluation set } \Psi$ .

The “Goodness” part says when both the evaluation set and  $X$  have many features and thus are rich then the function tends to output a larger satisfaction value. The “Dominance Part” outputs how dominant  $X$  is over the other alternatives in the attribute structure induced by  $\Psi$ .

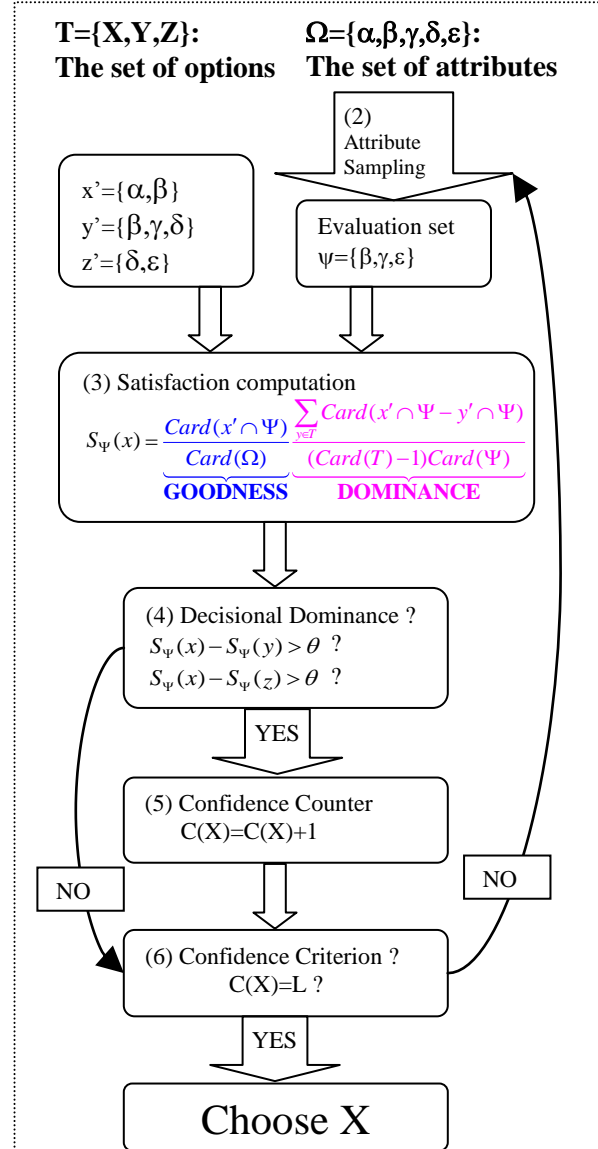

(4) A *decisional criterion*  $\theta$  is assumed. If  $S_\Psi(x) - S_\Psi(y) > \theta$  for all  $Y \in T - \{X\}$  then  $X$  is in the state of *decisional dominance*. If no option is dominant the process jumps to (6). Decisional dominance means that an option dominates the others in satisfaction at the moment.

(5) For each alternative, there is a *confidence counter*  $C(X)$ . If  $X$  becomes decisional dominant in (4), then a unit increment is added to  $C(X)$ . Race model is incorporated around (5) and (6).

(6) If  $C(X)$  reaches a *confidence criterion*  $L$ , then  $X$  is chosen else the process resumes from (2), where the regeneration of evaluation set  $\Psi$  is performed. The confidence criterion or threshold  $L$  represents decision quality: If the decision is momentous,  $L$  will be a high value, whereas if the decision is less important,  $L$  will be smaller. The depth of reconsideration processes are partially moderated by  $L$  and thus a merit of REGAL is that it encompasses the notion of decision quality.

When only one attribute is very important in decision, EBA, SDS, and REGAL tend to produce the same final choice.

**Counter Model** The loop between (6) and (2) constitutes a counter model (Smith & Van Zandt, 2000). The exact probability of choice is given in Appendix (Section 5).

**Figure 2: Outline of REGAL Model**

**Relation to Previous Models** Based on Manski (1977), several researchers have proposed conjunction models to make consideration sets (Andrews & Manrai, 1998; Gilbride & Allenby, 2004, 2006). *Subset Conjunction* proposed by Jedidi and Kohli (2005) is similar to the *evaluation set* in this paper. REGAL does not make consideration sets explicitly, but when  $y' \cap \Psi = \emptyset$  alternative  $Y$  is virtually excluded from the set of choice options and the remaining alternatives form a temporal consideration set. The major difference between REGAL and these previous models is that the consideration set is always temporary in REGAL.

### Simulation: Choice Set Effects

This section demonstrates how REGAL explains choice set effects (Roe, Busemeyer, & Townsend, 2001) and their interactions. Choice set effects have been studied on 2-dimensional continuous attribute spaces (Figure 3). Suppose

there are two options : A and B. Choice set effects (Similarity, Attraction, and Compromise effects) occur as a function of the location of new option C.

Both EBA and REGAL prefer discrete features and thus a special arrangement is needed to deal with continuous dimensions (See, Gensch & Ghose, 1992 for another approach). Basically, the continuous dimension is divided into segments and each segment is reinterpreted as a feature. For example, let  $A'=\{\alpha, \gamma, \delta\}$  and  $B'=\{\alpha, \beta, \gamma\}$  before the placement of C. If we place a new option  $C_1$ , the definition of segments and thus the features are changed accordingly (Figure 3) :  $A'=\{\alpha_1, \alpha_2, \gamma, \delta_1, \delta_2\}$ ,  $B'=\{\alpha_1, \alpha_2, \beta, \gamma\}$ , and  $C'=\{\alpha_1, \gamma, \delta_1\}$ , in this particular case.

**The Probability of Choosing a Feature** Let  $P(\tau), \tau \in \Omega$  be the probability that feature  $\tau$  is included in  $\Psi$ .  $P(\tau)$  is a function of feature importance or salience. In the present simulation, the length of feature would represent the salience, so that it is simply assumed :

$$P(\tau) = 1 - \exp(\text{length}(\tau) \times K_1) \quad K_1: \text{constant}$$

which is sub-additive (Rottenstreich & Tversky, 1997) in the sense that  $P(\alpha) \leq P(\alpha_1) + P(\alpha_2)$  when  $\alpha = \{\alpha_1, \alpha_2\}$ .

**Value Function and Satisfaction Function** The value (utility) of feature  $\tau$  is again assumed to be a function of the length of feature :

$$v(\tau) = K_2 \times \log(\text{length}(\tau)) \quad K_2: \text{constant.}$$

Using this function, the original binary version of satisfaction function (Equation (A.2) in Appendix) is converted into a continuous dimensional version:

$$S_\Psi(x) \equiv \frac{\sum_{\tau \in x \cap \Psi} v(\tau)}{\underbrace{\text{Card}(\Omega)}_{\text{GOODNESS}}} \frac{\sum_{\tau \in x \cap \Psi - y \cap \Psi} v(\tau)}{(\underbrace{\text{Card}(T) - 1}_{\text{DOMINANCE}}) \sum_{\tau \in \Psi} v(\tau)}$$

**Interactions of Choice Set Effects** Suppose that new Option C is placed at  $C_1$ . Attraction effect predicts  $P(A)$  will be larger while Similarity effect predicts  $P(A)$  will be smaller. If C is place at  $C_2$ , Similarity effect predicts  $P(A)$  smaller while Compromise effect predicts  $P(A)$  will be larger. If C is placed at  $C_3$ ,  $P(A)$  may become larger because C is dominated by both A and B but more strongly dominated by A than B, and there may be a slight similarity effect between C and B as well.

Apparently, in these cases choice set effects compete or collaborate and the choice probabilities should be determined as a non-linear function of *forces* that try to push up or down probabilities. In choice effect studies, *pure* conditions in which the effect of a single *force* becomes observable have been used. A next challenge should be to clarify the joint effects of choice set effects and the present study is the first such attempt.

## RESULTS

By moving Option C on the space (Figure 3), we can observe how the probabilities for Options A, B, and C change. REGAL can probe the joint effects by generating *probability topographies* (Figures 4, 5, and 6) calculated from Equation (A.3) in Appendix. Several detailed values for parameters are also shown in Appendix.

**Figure 3: Option representation on 2-dimensional attribute space.**

**Figure 4a: P(A) as a function of C location**

**Figure 4b: P(A) as a function of C location**

**Figure 5a:  $P(C)$  as a function of  $C$  location**

**Figure 5b:  $P(C)$  as a function of  $C$  location**

**Figure 6:  $P(C)$  as a function of  $C$  location when  $L$  is large ( $L=20$ ).**

Figures 4a (bird's eye view) and 4b (contour map) show the same topographic probability information. The probabilities are theoretical predictions in an ideal space

The reading of Figure 4a and 4b is a little confusing: they are showing  $P(A)$ , the probability that Option A will be chosen, *as a function of  $C$  location*. Therefore, the right lower high region, for example, should be read that “if you place  $C$  around here,  $P(A)$  will be high.” Figures 5a and 5b show  $P(C)$  as a function of  $C$  location. In this case, the figures give a natural interpretation. The graph for  $P(B)$  is omitted because it is an exact mirror image of Figure 4.

Major observations are as follows. 1) Strikingly high  $P(C)$  is obtained when  $C$  strongly dominates  $A$  and  $B$  (Figure 5b, upper right) and very low  $P(C)$  when  $C$  is dominated by both  $A$  and  $B$ . 2) Similarity effect is stronger than attraction effect (Figure 4b) and compromise effect is very weak (Figure 5b). Attraction effect was weak possibly because attraction and similarity effects compete in Figure 4b. 3) Increasing  $L$  made large probabilities larger and small probabilities smaller. As a result, the slope in Figure 6 became steeper. Psychologically, this would mean that deeper deliberation changes probabilistic choice into something akin to logical judgment, decreasing the chance of taking inferior options. Of course, these observations depend upon the present configuration of options, definitions of features, the shape of the value function, and the parameter values. More intensive search is needed to validate the model. Due to space limitation, RT predictions will be presented elsewhere.

## Discussion

It is well-known that MDFT model (Roe, et.al, 2001) and LCA model (Usher & McClelland, 2001) are able to mimic the three choice set effects. The present model is distinct both in architecture and in processing assumptions and can deal with, at least in theory, any number of options and attributes. Further, it can produce predictions for choice probabilities and decision times. This paper showed only qualitative validity of REGAL in an ideal theoretical space and empirical tests will be necessary in the future study.

## Appendix: Technical Details of REGAL

This part should be read with reference to Figure 2.

### (1) Initial setting

$T$ : the set of alternatives,  $\Omega$ : the set of attributes

### (2) Evaluation set construction

$\Psi$ : Evaluation feature set

$P(\tau)$ : The probability that feature  $\tau$  is included in  $\Psi$ .  $P(\tau)$  is an increasing function of feature importance or salience.

The probability of generating evaluation set  $\Psi$  is

$$P(\Psi) \equiv P(\Psi \leftarrow 2^\Omega - \phi) = \frac{\prod_{\tau \in \Psi} P(\tau) \prod_{\tau \notin \Psi} (1 - P(\tau))}{1 - \prod_{\tau \in \Omega} (1 - P(\tau))} \quad (A.1)$$

Important features tend to stay in  $\Psi$  and common features are not forcefully excluded.

(3) **Satisfaction function**  $S_\Psi(x)$  measures the degree of satisfaction and is a function of  $\Psi$  and  $X$ .

$$S_\Psi(x) \equiv \frac{\underbrace{\text{Card}(x' \cap \Psi)}_{\text{GOODNESS}}}{\underbrace{\text{Card}(\Omega)}_{\text{GOODNESS}}} \frac{\sum_{y \in T} \text{Card}(x' \cap \Psi - y' \cap \Psi)}{(\text{Card}(T) - 1) \text{Card}(\Psi)} \quad (A.2)$$

$\text{Card}()$  is the cardinality of a set. *Goodness* part takes a value in  $[0,1]$ : the value of 1 is obtained when  $x' = \Psi = \Omega$ , that is, alternative  $X$  is perfectly dominating the other alternative in the sense it has all relevant attributes, and the value 0 is obtained when  $x' \cap \Psi = \phi$ , that is,  $X$  has no relevant attributes under the current evaluation set. *Dominance* part represents the structural dominance of  $X$  over the other alternatives. This part also takes a value in  $[0,1]$ : the value of 1 is obtained when  $x' = \Psi$  and  $y' \cap \Psi = \phi$  for all  $Y$  except  $X$ , that is, alternative  $X$  is perfectly dominating the other alternative with respect to the current evaluation set, and the value of 0 is obtained when  $x' \cap \Psi - y' \cap \Psi = \phi$ , that is,  $X$  is totally dominated by the other alternatives under the current evaluation set.

(4) **Probability of decisional dominance** The probability that Alternative  $X$  becomes dominant,  $M_X$ , is defined as

$$M_X \equiv \sum_{\Psi \in 2^\Omega - \phi} P(X \text{ is decisional dominant} | \Psi) P(\Psi) \\ = \sum_{\Psi \in 2^\Omega - \phi} P(S_\Psi(X) - S_\Psi(Y) > \theta, \forall Y \in T - X | \Psi) P(\Psi)$$

where  $\theta \sim N(\mu, \sigma^2)$ : Decisional criterion that may fluctuate.

In the text, the variance is set to 0 and thus  $\theta$  is a constant.

(5) **Confidence counter  $C()$** . The loop between (6) and (2) in Figure 2 can be captured by a race model and an alternative that first reaches  $L$  is chosen, where  $L$  is a confidence criterion. From the standard result of Poisson counter model (Smith and Van Zandt, 2000), the final choice probability is given in closed-form by:

$$P(X) = \sum_{j_1=0}^{L-1} \sum_{j_2=0}^{L-1} \cdots \sum_{j_{X-1}=0}^{L-1} \cdots \sum_{j_{n-1}=0}^{L-1} \frac{1}{\prod_{k=1}^n j_k!} \prod_{k=1}^n \left( \frac{\lambda_k}{\sum_{i=1}^n \lambda_i} \right)^{j_k} \left( \frac{\lambda_X}{\sum_{i=1}^n \lambda_i} \right)^{j_n} \quad (A.3)$$

where  $n$  is the number of attributes and  $\lambda_k$ 's are Poisson strength parameters. Without loss of generality, we can set  $\lambda_k = M_k$ . The free parameters are  $L, \mu, \sigma^2$  and  $P(\tau), \tau \in \Omega$ . By adjusting them, we can examine whether REGAL can mimic the three choice-set effects. In the simulation,  $L=5$ ,  $\mu=0$ , and  $\sigma^2=0$  were used.

# Creative Process of Improvised Street Dance

## Abstract

This paper presents findings from our empirical study of the creative process of improvisation, which has rarely been the subject of research in cognitive science. In this study, battle scenes in street dance were selected as an example of improvised performances. We conducted an experiment to investigate real-time cognitive processes. The results indicated three features: 1) Dancers mainly used well-practiced patterns, and discovered new patterns of dance; 2) In the process of discovering new patterns, dancers often utilized errors in their performance; 3) The processes of discovery were different in the performance of one dancer (solo scene) and the performance of two dancers (battle scene). In solo performance, dancers discovered new patterns by concentrating on their patterned dance. In battle performance, dancers discovered new patterns by utilizing stimuli from the situation (e.g. the music, their opponent) and using errors as an opportunity to loosen the constraints of their well-practiced patterns.

**Keywords:** Improvisation; Street dance; Personal discovery; Utilizing errors; Battle scenes

## Introduction

Improvisations such as jazz or improvisational dance or drama are complicated human activities which seldom become research subjects in cognitive science. However, improvisations are thought to be the origin of many activities in the arts (see Bailey, 1980). The moment when a person gains new ideas is considered to be related to improvisational patterns (Pressing, 1984). Based on these suggestions, improvisations are thought to be a core element in human creativity.

## Features of improvisational activities

Most previous studies dealing with improvisation have investigated jazz music (e.g., Mendonça & Wallace, 2004; Tayanagi, 2010; Weisberg et al., 2004). Mendonça & Wallace (2004) investigated the duo performance of jazz musicians, and suggested that musicians use some fixed patterns in improvisation. They also suggested that a musician utilizes the music of the other musician as a guideline for his own musical performance.

Weisberg et al. (2004) examined records of the improvisations of professional jazz musicians, and

suggested that they often utilized specific formulas (50-90% of each performance) in their performances.

Tayanagi (2010) investigated the literature and the biographies of professional jazz musicians theoretically, and claimed that accepting inevitable errors in performance and utilizing these errors is very important for innovation and the production of new patterns in jazz music. This suggestion is consistent with the claim of Pressing (1984).

Bailey (1980) investigated the cognitive process of improvisation by interviewing professional musicians in many genres of music. Based on anecdotal evidence, he suggested that there are differences in music between improvisations by one person and improvisations by multiple persons.

From these suggestions, we could summarize the features of improvisations as follows. 1) Performers use fixed-patterns. 2) Performers utilize the errors which are inevitably generated to make new patterns. 3) The number of person participating in the improvisation makes some difference.

## Personal discoveries of new ideas in improvisations

In this study, we investigated the process of improvisational activities, paying special attention to “personal discoveries”. “Personal discovery” is defined as the discovery of new ideas, expressions or techniques occurring in creative activities, which the performers (creators) did not envisage prior to these activities. This concept mostly focused on the cognitive process of creators, and from this point of view, personal discovery is strongly related to Psychological Creativity (creativity which results in processes or products that are new and useful to the creators themselves), as Boden (1991) suggested. The personal discovery in dance is a movement which may not be new in a general sense, but is new to the dancer performing it. Many researchers have suggested that unpredicted findings like personal discoveries play important roles in creating new products or making scientific discoveries (e.g., Dunbar, 1993; Suwa & Tversky, 1997). In the case of improvisations, personal discoveries also play important roles when creating new products, expressions or techniques which performers did not envisage in advance (Bailey, 1980). In this sense, improvisation involves personal discovery as its core.

## Breakdance as an improvisational activity

This study deals with the battle scenes of breakdance (a major genre in street dance) as an example of improvisation. Breakdance first appeared in Manhattan in the late 1970s, and has spread widely around the world. This dance consists of four patterns: entry (dance in a standing position), footwork (dance performed on the floor), power moves (dance with acrobatic movements like rolling), and freeze (dance poses held in acrobatic positions) (OHJI, 2001). In the battle scenes, dancers stand facing one another and perform their improvisational dance for 30-40 seconds in turns. Dancers in break dance have to perform while listening to unfamiliar music, communicating with an opponent, and responding to the dance of the opponent. Hence, the battle scenes of breakdance are highly improvisational. Therefore, it is appropriate to use battle scenes as the object of research into improvisational activities.

### Purposes of this study

This study investigates the cognitive processes of dancers in battle scenes of breakdance, which are considered to be an example of an improvisational activity. Specifically, we focus on three questions based on the findings of previous studies: 1) How often are fixed patterns of dance used? In previous studies, it has been hypothesized that fixed patterns are used in improvisation more than 50% of the time. 2) Do dancers utilize the errors which are inevitably generated in improvisational dance to find new patterns of dance movements? If so, how do they utilize these errors? 3) Are the improvisational activities of a solo dancer different from the improvisational activities of multiple dancers? In order to answer these questions, we conducted an experiment with dancers.

## Methods

### Participants

Fourteen semi-expert dancers participated in this experiment (mean age 24.5 ( $SD=3.8$ ), mean experience 6.5 years ( $SD=4.4$ )). The level of skill of the dancers was evaluated from the following two aspects: the acquisition and use of the basic skills required for the four patterns of dance, and the acquisition and use of advanced skills relating to power moves (highly skilled movements). The evaluation was conducted by the first author using a videotape recorded during the experiment. As a result of this evaluation, we found that all the subjects had advanced levels of skill in addition to the basic skills of breakdance and were able to perform various patterns of movements in breakdance.

### Procedure

In this experiment we set two conditions, the solo scene condition and the battle scene condition. The only difference between the solo scene and the battle scene was that there was no opponent (dance partner) and so no dance by an opponent in the solo scene. This solo condition was

set to investigate question 3, relating to differences arising from the number of persons. Both scenes used the same music (Bomb the Bass, "Megablast"). The experiment was conducted in one room of the gymnasium of the university. The room size was 14.4 x 14.5 meters. The performances were recorded on video.

This experiment consisted of three different sessions: 1) Preparative session (explanation of experimental procedure and warm up); 2) Performance session; 3) Post-performance session (dancers' reflections on their own movements and thoughts during the dance performances).

- 1) We explained to the participants the outline of this experiment, i.e., the design of the experiment (two independent variables, solo scene and battle scene), and the resting time between the two sections. Then, we told the subjects to take about 30 minutes to warm up.
- 2) Each dancer performed the solo or the battle scene. For each scene, the dancers performed for about 30-40 seconds and then took a 30-40 seconds interval (in the solo scene, they just waited without dancing, and in battle scene, they watched the opponent dancing). They repeated this set three times. Music was continually playing during each scene. Just before the performance, we explained to the dancers the details of each scene (three sets of dances and intervals), and asked them to perform naturally as in a usual battle scene. For the solo scene, we instructed the dancers to perform as if it were a battle scene, pretending there was an opponent.
- 3) We asked the dancers to reflect on their dance performances and report their thoughts during the dance (Figure 2). First, the dancers watched videos of their dance performances, and they segmented their dance movements into meaningful units. Then the dancers evaluated each dance segment using a creativity score (novelty and dexterity), and reported what they were thinking while dancing each segment.

We conducted these three sessions for one scene (solo or battle), took a break of about an hour, then repeated sessions 2 and 3 for the other scene. The order of the scenes was counterbalanced.

### Outline of analyses

In this study, we analyzed the processes of improvisation with three sets of data: 1) Creativity score of dancers (self-evaluation); 2) Self-report of cognitive process by dancers (report of thoughts); 3) Categorization of dance movements based on the usage of the four types of movements (categorization of dance movements).

1) We used the data from the creativity scores of dancers. Through the use of these data, we aimed at investigating the features of dance movements from the dancers' own viewpoints. The objects of the creativity score (novelty<sup>1</sup> and

<sup>1</sup> This consists of 3 rating scores: Dance 1) is well practiced; 2) is not well practiced, but has been performed before; 3) has never been performed. We used these scores because in the preliminary interviews with other dancers, the dancers told us that to judge the

Table 1. Mean number and percentage of dance movements corresponding to each novelty score (sum of three trials)

<i>Scene</i>	<i>Score 1 (well-practiced)</i>	<i>Score 2 (not well-practiced, but has been performed before)</i>	<i>Score 3 (has never been performed)</i>
Solo	8.2(4.64) 66%	3.1(2.88) 25%	1.1(1.41) 9%
Battle	8.1(4.95) 66%	3.0(1.66) 25%	1.1(1.29) 9%

Table 2. Mean number and percentage of dance movements corresponding to each dexterity score (sum of three trials)

<i>Scene</i>	<i>Score 1 (very poor)</i>	<i>Score 2 (poor)</i>	<i>Score 3 (moderate)</i>	<i>Score 4 (good)</i>	<i>Score 5 (very good)</i>
Solo	1.64(1.60) 13%	3.36(1.22) 27%	4.64(3.05) 37%	2.29(2.27) 18%	0.57(0.94) 5%
Battle	2.00(2.18) 16%	3.50(2.03) 29%	4.29(2.92) 35%	2.00(2.25) 16%	0.43(0.85) 3%

dexterity<sup>2</sup>) were based on previous studies of creativity (e.g., Finke et al., 1992).

We summed up the data of the creativity scores and conducted statistical analyses. In addition, we identified dance movements with high creativity scores (2 or 3 for novelty and 4 or 5 for dexterity), and analyzed the data. These high-scoring dance movements reflect the dancers' personal discoveries, because they reported the new and useful movements that they had "discovered". By analyzing them, we were able to investigate the features of "personal discoveries" in each scene.

2) We used the answers to the question, "What were you thinking while you were dancing these particular movements?" in the report on cognition. In the analyses, we categorized the focus of consideration of the dancers while dancing and classified each statement according to the category. By analyzing what the dancers were giving their consideration, we were able to investigate the points about which the dancers thought deeply in each scene. In addition, we identified the statements about high-scoring dance movements which were thought to reflect their personal discovery, and analyzed them using these categories. By analyzing them, we were able to investigate the focus of consideration of the dancers when generating new patterns.

3) We used the data from the performances of the dancers (dance movements in performance sessions), and categorized them into the four types of breakdance. By comparing the number of movements of each type between the solo scene and battle scene, we were able to investigate the nature of dance movements in each scene objectively.

## Results and Discussion

Before analyzing the details of the data, we compared the basic features of both scenes (the time of performance, the number of dance segments). We conducted a paired *t*-test on

these data and found that there was no statistical difference between the two scenes (solo: 95.4 (23.26)<sup>3</sup> seconds, battle: 86.3 (16.52) seconds,  $t(13) = 1.68$ ,  $p = .12$ ) (solo: 12.5 (5.07), battle: 12.2 (4.93),  $t(13) = 0.75$ ,  $p = .75$ )<sup>4</sup>

### Creativity score of dancers

#### Novelty score (Table 1)

Using a sign test, we conducted a contrast analysis of each novelty score (score 1 - score 3) in the solo scene and the battle scene. As a result, we found that there were no differences between the two scenes (the *p*-values of scores 1, 2, 3 were  $p = .79$ ,  $p = .58$ ,  $p = 1.00$ ). Then we examined the number and percentage of each novelty score in each scene to determine which scores frequently appear. As shown in Table 1, there were high degrees of appearance of score 1 in both scenes. The percentages of score 1 are 66% in mean rate in both scenes. These results show that dancers mainly use well-practiced, somewhat patterned dance movements in improvisational activities.

#### Dexterity score (Table 2)

Using a sign test, we conducted a contrast analysis of each dexterity score (score 1 - score 5) in the solo scene and the battle scene. As a result, we found that there were no differences between the two scenes (the *p*-values of scores 1, 2, 3, 4, 5 are  $p = .79$ ,  $p = .58$ ,  $p = 1.00$ ,  $p = 1.00$ ,  $p = .63$ ). Then we

<sup>3</sup> In this study, we used the mean score which sums up the three trials in the performance session in each scene.

<sup>4</sup> These data have high degrees of *SD* and are thought to be out of Gaussian distribution. We conducted a sign test to eliminate the influence of individual differences. Analyses show the same results as the *t*-test (time of performance:  $p = .12$ , number of dance movements:  $p = .75$ ). The reason why high degrees of *SD* appear seems to be as follows. Each dancer performs a trial using a subjective time scale acquired through his/her dance experience. Each one may have a different subjective time span. The sizes of chunks of dance that dancers think of as a dance unit may differ individually. Based on this supposition, we employed a statistical test that utilizes the comparison of each individual (like a sign test).

practice level, a 3-point rating was much more suitable than a 5-point rating.

<sup>2</sup> This consists of five rating scores: Dance is: 1) very poor; 2) poor; 3) moderate; 4) good; 5) very good).

Table 3. Definition of the categories and mean number (sum of three trials)

<i>Higher category</i>	<i>Lower category</i>	<i>Definition</i>	<i>Solo</i>	<i>Battle</i>
A: Consideration of their own dance	a: Well-practiced dance movements	Dancers consider well-practiced dance	3.1 (2.57) 27%	2.4 (2.03) 21%
	b: New patterns	Dancers give consideration to new patterns of dance	0.6 (0.93) 4%	0.5 (0.76) 4%
	c: Dance composition	Dancers give consideration to the composition of their dance	1.6 (1.09) 10%	0.8 (0.70) 6%
B: Consideration of information about the situation	d: Music	Dancers give consideration to the music	2.5 (2.14) 19%	2.6 (2.34) 23%
	e: Opponent (partner)	Dancers give consideration to their partner	0.2 (0.43) 2%	1.7 (1.20) 14%
	f: Physical position	Dancers give consideration to their physical position	1.4 (1.28) 10%	2.1 (1.46) 16%
C: Consideration of other factors	g: No specific consideration	Dancers give no consideration to anything specific	2.3 (1.98) 21%	1.5 (2.35) 11%
	h: Other factors	Dancers give consideration to other factors	0.9 (1.10) 7%	0.5 (0.65) 5%

examined the number and percentage of each dexterity score in each scene. The results showed that scores 2 and 3 frequently appeared in both scenes. Hence, we are able to suggest that dancers mainly use dance movements which show similar dexterity to well-practiced dance movements.

#### **Dance movements corresponding to personal discoveries**

We identified high creativity scoring dance movements (2 or 3 for novelty and 4 or 5 for dexterity) and examined their rates of appearance in both scenes.

The results show that there are 14 high-scoring dance movements (8% of all the dance movements) in the solo scene, and 17 high-scoring dance movements (10% of all the dance movements) in the battle scene. Even in the short-time performances (80-100 sec.) in this experiment, dancers found new patterns and made personal discoveries. The result that there are high-rated uses of patterned dance movements indicates that dancers in improvisation mainly use patterned dance movements and gradually find new patterns through improvisation. To compare the rate of appearance between each scene, we conducted a sign test and found that there was no statistical difference ( $p=.51$ ).

#### **Consideration of dancers in performances**

##### **Analyses of statements about all dance movements (Table 3)**

The  $\kappa$  coefficient was calculated by the first author and a researcher who did not know the purpose of this study, using about 20% of all the data, 70 dance movements, to check the reliability of the rating. The  $\kappa$  coefficient was 74.1%, which guarantees the reliability of the ratings. Using a sign test, we conducted a contrast analysis to compare the number of each category in the solo and the battle scenes. The results show that there were statistical differences in c)

Consideration of dance composition, e) Consideration of the opponent, f) Consideration of the dancer's own physical position ( $p=.039$ ,  $p=.003$ ,  $p=.065$ ). In the solo scene, dancers often think about the composition of whole dance movements. In contrast, in the battle scene, the dancers consider information about the situation (opponent, physical position).

We also compared the numbers and percentages in each category in each scene to determine frequently appearing categories. As shown in Table 3, in the solo scene, a) Consideration of well-practiced dance movements, d) Consideration of the music, g) No specific consideration, and in the battle scene, a) Consideration of well-practiced dance movements, d) Consideration of the music, e) Consideration of opponent, f) Consideration of the physical position appeared more frequently than other categories. Thus, we conclude that in the solo scene, dancers think about well-practiced dance movements or the music, and construct performances considering the whole composition of their dance movements. In contrast, in the battle scene, dancers consider the situation (music, opponent, physical position) more closely than their own movements. The reason why these differences were shown was as follows. Since in the solo scene with no opponent, dancers did not have to communicate with the opponent, they could concentrate on their own performance. However in the battle scene, dancers need to communicate with the opponent and to deal with changes in the situation (OHJI, 2001), so they concentrated on information about the situation. We describe the details of these processes below.

##### **Analyses of statements about dance movements corresponding to personal discoveries**

Table 4. Example statement about the process of personal discovery in a solo scene

S171: Why did you rate this dance as novelty score 2?
G173: What should I say? I did an uprock in this dance. Usually, I don't perform this movement a lot.
S172: Is that this movement? (Watching the video).
G174: Yes. Because of this movement, I rated this dance as score 2.
S173: Why did you suddenly sit down? When you performed this movement, what were you thinking?
G175: I thought that in trial 1 or 2, I had danced in a standing position a lot, and I didn't do a move like sitting down. So I did this sitting movement in trial 3.
S174: So was this a movement which you tried to do intentionally?
G176: Yes, I decided on it just before the movement.

In this section, we focus on the objects of consideration of dancers in personal discoveries by analysing the data of high creativity score dance movements. Because of the low number of corresponding dance movements, we could not find a statistical difference between the two scenes. However, the results suggest that c) Consideration of composition, d) Consideration of the music, and g) No specific consideration frequently appeared in the solo scene (numbering 4 dance movements, 5 dance movements, 4 dance movements, out of a total of 14 dance movements). In the battle scene, d) Consideration of the music, e) Consideration of the opponent, f) Consideration of physical position frequently appeared (respectively, 8 dance movements, 3 dance movements, 4 dance movements, out of a total of 17 dance movements). From these results, we conclude that dancers consider their dance movements and make personal discoveries in the solo scene, while dancers in the battle scene consider information about the situation more closely and make personal discoveries.

Besides these implications, two statements (Table 4, 5) about personal discoveries suggest that in the solo scene, dancers considered the context of each dance movement, and intentionally made new patterns of dance movements. In contrast, in the battle scene the dancers tried to consider the situation, and deal with changes in the situation. However, they were able to make use of only limited patterns of well-practiced dance movements. Failure in dynamical dance movements such as power moves (one of the four core patterns in breakdance) leads to a loosening of the restrictions of the patterned dance movements, and the dancers are able to find new patterns.

#### Differences between the solo scene and the battle scene

We investigated the reasons why differences between the solo scene and the battle scene existed. One participant clearly mentioned how the two scenes differed (Table 6). In

Table 5. An example statement about the process of personal discovery in a battle scene

S141: Do you usually find new patterns in a battle scene?
B144: I usually don't use only fixed patterns. When performing, I just think what techniques (movements) I should use next. So, that was it. I just wanted to do a short one. I also thought that I would use free and flexible dance movements in the rest of the performance. I'm always ready for freeze movements anytime when it's necessary.
S142: So, do you dance with flexible combinations of movements when you dance freely?
B145: Yes, I always use flexible combinations, maybe. However, even in those combinations, I might have a tendency to use some particular combinations of fixed patterns.
S143: What do you think about this dance in terms of your tendency?
B146: This dance is not in keeping with that tendency. It goes against the tendency. T (the opponent) might have thought that this dance looked great.
S144: Why do you think you performed dance in this way?
B147: Hmm, my physical position after doing Trax <sup>5</sup> in that situation was probably a little different from the usual one. I didn't think of anything when performing.
S145: You didn't think of anything during the performance, but the physical position was different from usual.
B148: It's different, but maybe the music is one of the factors that caused it.

the solo scene, which had no opponent, dancers tended to perform well-practiced dance movements, not to fail and to arouse the audience, and they concentrated on their own performance. In contrast, in the battle scene, the dancers had to consider the improvisational communications with their opponent, which were thought to be an important factor in the battle scene, and they tried to think about the information (music, opponent) and to perform dynamical, impressive dance movements such as power moves.

#### Features of dance movements in each scene

We conducted a contrast analysis to compare the features of dance movements in solo and battle scenes in terms of the frequency of the four types of movement. The results of the sign test show that there were statistical differences in entry (dance movements in a standing position) (solo scene: 42.4 (22.18) seconds, battle scene: 33.3 (12.18) seconds) and power moves (dance with acrobatic movements like rolling) (solo scene: 15.1 (13.5) seconds, battle scene: 17.5 (10.55) seconds) ( $p=.057$ ,  $p=.092$ ). These results suggest that dancers perform dynamical movements (like rolling or

<sup>5</sup> One of the dance movements which is categorized as a power move.

Table 6. An example statement about the difference between the two scenes

M94: In the battle scene, I usually compose my dance movements, taking the situation of the place into account, while watching the dance of opponent. But in the solo scene, since I'm used to performing in public, I use well-practiced and skilled dance movements.
S94: You use mainly well-practiced dance movements?
M95: Yes, it was so in the solo scenes. In the battle scene, I wanted to pay more attention to my partner.
S95: What do you think makes this difference between the two scenes?
M96: Partners are an essential part in battle scenes. Communication with the partner is important and an interesting aspect of the battle scene. A dancer who is good at that communication looks cool, I think. In the solo scene, however, to be applauded is important, and I want to give a skilled performance to accomplish it. So I tend to use well-practiced dance movements.

jumping) more frequently in the battle scene. This result matches with the inference of the previous section, which suggested that dancers considered the opponent and tended to perform dynamical dance movements more frequently in the battle scene.

### General Discussion

This study has investigated the cognitive processes of dancers in improvisational activities such as the battle scene of breakdance, focusing on personal discoveries. The results have shown the following three findings. 1) Dancers mainly used fixed patterns of dance movements (about 60-70% of the whole dance) and gradually found new patterns of dance movements in improvisational activities. 2) By failing in dynamical movements, they were able to loosen the constraints of fixed patterns of dance movements, and found new patterns. 3) The processes of personal discovery (finding new patterns) varied with the presence of an opponent (partner). With reference to point 3, the following two processes have been revealed. In the absence of an opponent, the dancers thought about their own dance movements, and found new patterns by considering carefully the composition of their dance movements. In presence of an opponent, dancers considered the information about the situation (such as the music, opponent), and tended to perform dynamical dance movements more frequently. Then, when failing in these dynamical movements, they had to continue their performance from the present physical position that was different from their dominant (fixed) patterns, and they were able to find new patterns that were beyond fixed patterns.

This study has contributed new and clear findings about the features of improvisation based on the findings of previous studies (e.g., Mendonça & Wallace, 2004; Pressing, 1984; Tayanagi, 2010). Through a concrete example, we

describe the process by which dancers utilized errors to make new movement patterns, relaxing the constraints of their fixed patterns. In addition, we have focused on the original aspect of "the differences between improvisational activity of one person and that of multiple persons". The fact that there are differences between solo and collaborative activities has been suggested in many domains, especially in the domain of creativity (e.g., Okada & Simon, 1997, in scientific discovery). However, there has been no clear suggestion of these differences in the domain of improvisation. This study contributes original insight into the domain of improvisation.

In order to acquire more detailed understandings of improvisation, further studies are needed to solve problems such as the problem of generalization and research method.

### Acknowledgments

We would like to express our gratitude to all the participants for having spent so much time on our research and for giving us extremely useful suggestions about breakdance.

## Abstract

Autonomous learning is the ability to learn effectively without much external assistance, which is a desirable characteristic in both engineering and computational modeling. We extend a constructive neural-learning algorithm, sibling-descendant cascade-correlation, to monitor lack of progress in learning in order to autonomously abandon unproductive learning. The extended algorithm simulates results of recent experiments with infants who abandon learning on difficult tasks. It also avoids network overtraining effects in a more realistic manner than conventional use of validation test sets. Some contributions and limitations of constructive neural networks for achieving autonomy in learning are briefly assessed.

**Keywords:** autonomous learning; abandoning learning; constructive neural networks; SDCC.

## Introduction

Autonomous learning is the ability to learn effectively without much external assistance. As such, autonomy is a desired quality in fields such as machine learning and artificial intelligence where the effectiveness of learning systems is seriously compromised whenever human intervention is required. It is likewise a desired feature in cognitive science where a goal is to understand the adaptive functioning of human and other biological agents in their natural environments. An important characteristic of autonomous learners is that they can shape their own learning and development, in large part by choosing what problems to work on. Such choices include selecting a problem to learn and deciding whether to continue learning on the selected task or abandon it in favor of something else.

## Knowing When to Quit

Knowing when to stop learning has two obvious components – quitting when the problem has been mastered and when it is unlikely to be mastered. In the constructive neural networks that we favor, victory is declared, and learning terminated, when the network is correct on all training examples, in the sense of producing outputs that are within some score-threshold of their target values (Fahlman & Lebiere, 1990; Shultz, 2003).

Cessation of learning without mastery is considerably more problematic, despite being an important component of autonomous learning in biological agents. It may be useful to analyze such early quitting in terms of costs and benefits. The total cost of learning can be conceptualized as energy expenditure (of the learning effort) plus opportunity cost (the value of the best alternative not chosen, whether other learning or exploitation of resources):  $Cost_{Total} = Energy_{Learn} + Cost_{Opportunity}$ . Then the net payoff of learning is the benefit of successful learning minus the total cost of learning:  $Payoff_{Net} = Benefit_{Learn} - Cost_{Total}$ . In continuing to work on an unlearnable problem, there would be a large negative payoff, cost without benefit. Having started to learn such a difficult problem, it could be sensible to abandon it when lack of progress becomes evident.

## Previous Work on Abandoning Learning

Recent computational modeling does suggest that a key factor in deciding to abandon learning early is whether learning progress is being made (Schmidhuber, 2005, 2010). In that work, learning progress is monitored by tracking the first derivative of error reduction to identify intrinsic rewards, while a reinforcement-learning module selects actions to maximize future intrinsic rewards. These models curiously conflate novelty with learning success, but it seems more correct to base novelty on initial error, and compute learning success as recent progress in error reduction. These models also include a reinforcement-learning controller that selects actions, and an external network to track learning progress. It seems simpler to continue learning by default until lack of progress is detected, perhaps in terms of stagnation in error reduction.

In an idealized learning model, infant looking was modeled by information-theoretic properties of stimuli (Kidd, Piantadosi, & Aslin, 2010). The negative log probability of an event (corresponding to the number of bits of information conveyed by a stimulus) was conditioned on observing previous events. The larger the negative log probability, the more surprising the current event. As predicted, 7- to 8-month-old infants were more likely to look away from either highly informative or uninformative events. The authors dubbed this the *Goldilocks* effect as

infants prefer to work on tasks that are neither too easy nor too difficult, but just about right in terms of complexity. Although interesting and consistent with an idealized statistical model, these findings are not tied to any neural computational mechanisms. Also, this model is presumably restricted to repeated sequences of events.

Other recent experiments reported that 17-month-olds attend longer to learnable versus unlearnable artificial-language grammars, taking more trials and more time on grammars in which a valid generalization over input utterances could be made (Gerken, Balcomb, & Minton, 2011). Thus, there is now independent evidence that infants may have an implicit metric of their learning progress and can direct their attention to more learnable material.

### Constructive Artificial Neural Networks

Constructive artificial neural networks (CANNs) grow a network topology while learning, inspired by principles of brain function and statistical mechanics. Among the attractive features of CANNs are graded knowledge representations, capacity for change and self-organization, and neurological plausibility. CANNs such as cascade-correlation (CC) grow by recruiting new hidden units whose activity correlates with network error (Fahlman & Lebiere, 1990). An extension, sibling-descendant cascade-correlation (SDCC), dynamically decides whether to install a newly recruited unit on the current highest layer (as a sibling) or on its own higher layer (as a descendant), thus optimizing the network topology for the problem being learned (Baluja & Fahlman, 1994). Unit recruitment corresponds roughly to processes of neurogenesis and synaptogenesis in the service of learning (Shultz, Mysore, & Quartz, 2007). Such CANNs have been used to simulate many cognitive, linguistic, and social phenomena while addressing important and longstanding issues about development and learning (Shultz, 2003; Shultz & Fahlman, 2010). They have also yielded testable predictions, many of which have been confirmed in psychological research. Moreover, CANNs have also made considerable progress on several aspects of autonomous learning, including network construction in which new abilities are built on top of earlier achievements.

In the present work, we extend SDCC to abandon learning that is failing to make progress. This is a natural extension for SDCC, which already is able to change phases when it detects lack of progress. Both CC and SDCC operate in two phases: output phase, in which connection weights entering output units are adjusted to reduce network error, and input phase in which weights entering hidden units are adjusted in order to increase the covariance between candidate-unit activation and network error, which ends up recruiting the candidate that best tracks network error. Output phase ends when error reduction stagnates, whereas input phase ends when the covariances between candidate activation and network error stop changing.

We hypothesized that, if error stagnation continues even after recruitment, this could additionally signal that the problem might be unlearnable. This would be the case, for

example, on problems with a random structure and insufficient regularities. Of course, some potentially learnable problems are so difficult that their patterns may only seem random. In either case, learning may be frustratingly slow and thus signal to stop and turn to something else more feasible. Here, we apply our extended algorithm to learning problems of varying randomness, discuss its potential to cover the infant experiments just reviewed, and briefly assess the overall ability and limitations of CANNs to learn autonomously.

## Method

### Algorithm Extension for Abandoning Learning

As noted, each of the two phases in CC and SDCC assesses progress within a phase. We define a learning cycle as an input phase, which recruits a hidden unit, followed by an output phase, which employs the new recruit to help reduce network error. (The first learning cycle has only an output phase, and no input phase.) To assess learning progress across learning cycles, we implemented a new, outside loop to assess progress at the end of each output phase, according to the following algorithm, in which a counter is initialized to 0:

If first learning cycle, then record current error and continue to input phase

Otherwise, compare current error to previous error as absolute difference

If absolute difference > threshold  $\times$  previous error, then reset counter to 0 and continue to input phase

Otherwise,

If counter = patience, then abandon learning

Otherwise, increment counter by 1 and continue to input phase

This algorithm is analogous to the progress-assessing loops already used in the output and input phases of CC and SDCC, which compute an absolute difference between a current and previous measure (network error for output-phase and learning-cycle loops, covariance for input-phase loops), and test if this difference is greater than a threshold proportion of the previous value. If the absolute difference exceeds this product, learning continues. If it does not exceed this product, then there is a check to determine if a patience parameter value has been reached. If patience has been exceeded, then the current loop is terminated; otherwise the patience counter is incremented by 1 and learning continues. Resetting the counter to 0 whenever the threshold proportion is exceeded insures that the number of cycles without exceeding the threshold proportion must be consecutive rather than sporadic. Although we rarely alter the threshold and patience parameters for output and input phases, here we do explore some parametric variation for assessing progress across learning cycles.

### Continuous XOR

We tested our extended algorithm on a continuous version of the exclusive-or (XOR) problem. This is a well

understood problem in which the simplicity of binary XOR is replaced by a more complex continuous version (Shultz & Elman, 1994; Shultz, Oshima-Takane, & Takane, 1995). Starting from 0.1, input values are incremented in steps of 0.1 up to 1, producing 100  $x, y$  input pairs that are partitioned into four quadrants of the input space, as illustrated in Figure 1. There is a single output unit with a sigmoid activation function. Values of  $x$  up to 0.5 combined with values of  $y$  above 0.5 produce a positive output target (0.5), as do values of  $x$  above 0.5 combined with values of  $y$  up to 0.5. Input pairs in the other two quadrants yield a negative output target (-0.5). These constitute the training patterns for conditions that are completely learnable.

Figure 1. Schematic drawing of the continuous-XOR problem. Gray sectors yield a positive output while white sectors a negative output.

To implement problems of different levels of difficulty, we vary learnability, defined as the percentage of target outputs that are not randomly selected: 0, 25, 50, 75, 80, 85, 90, 95, or 100. If a fresh random number in the range  $[1, 100] \geq$  the particular learnability percentage, then the output target (-0.5 or 0.5) is selected by a .5 chance.

Generalization test patterns are generated by incrementing  $x$  and  $y$  values by 0.1 to .94 starting from 0.14. There are 81 such test patterns, all with correct outputs.

In preliminary simulations, it became apparent that learning results were also sensitive to variation in the threshold parameter, so we varied threshold systematically (.05, .1, .15, .2, and .3), while holding patience at 2.

## Results

We do not present all of our results here, but only those needed to make important points about basic principles.

### Learning Threshold of .15

Typical training-error results are plotted in Figure 2 for two networks, one exposed to patterns with 50% learnability and the other exposed to patterns with 100% learnability. Learning threshold is here set to .15. The diamonds just above the error curves indicate the particular output-phase epochs at which a hidden unit is recruited. As is typical for all threshold values, error is reduced much further with full learnability than with 50% learnability. Moreover, as is typical for thresholds of .1 and higher, learning is abandoned much earlier with 50% learnability than with 100% learnability. These results suggest that the extended

algorithm is effective at detecting lack of progress in learning and show what underlies grouped results to follow.

Figure 2. Training error in two networks. With 50% learnability, learning stops at 99 epochs. With 100% learnability, learning stops at 420 epochs.

To see a more general picture, mean per-pattern training error for 20 networks under each learnability condition is plotted in Figure 3, again for a learning threshold of .15. Per-pattern error for a network is computed by dividing total network error by the number of patterns. Each curve is cut off at the mean number of output-phase epochs to abandon learning for that level of learnability, even though some networks surpass this number. Figure 3 provides a more complete demonstration that error reduction is greater with higher learnability and that the extended algorithm is effective at detecting lack of learning progress. Generally, the lower the learnability, the earlier learning is abandoned, at least up to 90% learnability.

Figure 3. Mean per-pattern training error for 20 networks under each learnability condition over learning cycles.

Mean learning times are shown in Figure 4, which plots the mean output epochs and SE bars for the same 20 networks. This shows more abstractly that low levels of learnability lead to early abandonment of learning.

Moreover, the inverted U-shaped curve reveals a substantial Goldilocks effect wherein networks show more sustained learning for problems of moderate difficulty, peaking at 90% learnability.

Figure 4. Mean output epochs (with SE bars) for 20 networks with learning threshold of .15.

However, in these simulations, the prolonged learning characteristic of the Goldilocks peak does not often yield superior performance. This is illustrated for these same networks in Figure 5, which plots mean per-pattern test error for each learnability condition. Notice the rise in error on test patterns for learnability conditions in the 50-90% range. Such increases in test error over training suggest that networks are over-fitting the training patterns and starting to memorize the random training patterns instead of abstracting a function to account for the examples. Their earlier success in bringing error down is presumably due to abstracting the continuous-XOR function. But from then on, their only recourse is to start memorizing the random patterns. At 0% learnability, it is impossible to abstract even a basic idea of the exclusive-or problem.

Figure 5. Mean per-pattern test error averaged across 20 networks under each learnability condition.

A rise in test error in what is typically called the validation test set is conventionally used by programmers to determine when to stop network learning. This can be particularly important when using static networks with

back-propagation, which have no natural stopping point and where there is no a priori idea of how many hidden units with which to equip a network. Such validation test sets are ordinarily unnecessary for CANNs, which start small and keep growing until the problem is learned. With substantial numbers of random patterns to be memorized, as here, it can be beneficial to also use test error as a training aid, even for CANNs. With a learning threshold of .15, the extended SDCC algorithm was unable to detect, from training error alone, that learning was not progressing, in the sense of generalization ability. Although validation test sets are useful for programmers, they are unrealistic for autonomous learners. Whenever target values and the resulting error signals are available, it is likely that learners would use them to adjust connection weights, thus effectively eliminating such examples from the validation test set.

### Learning Threshold of .3

This raises the question of whether other, less sensitive learning-threshold values could be used to curtail learning investment in unproductive tasks like our 50-90% learnability conditions. The answer, as revealed in Figure 6, is yes for a learning threshold of .3. In this case, there are no general increases in test error, except at 0% learnability.

Figure 6. Mean test error averaged across 20 networks under each learnability condition.

However, the Goldilocks effect for these same networks disappears, as revealed in Figure 7. The learning-time peak is now at 100% learnability as all other conditions have abandoned learning earlier. More generally, we find a trade-off between the Goldilocks effect and avoidance of rising test error. As learning threshold increases, the likelihood of finding a Goldilocks effect drops.

## Discussion

### Interpretation of Results

Our results show that monitoring progress across learning cycles can be used to abandon learning that is unlikely to be successful. This is both realistic and adaptive because, with many problems and domains to learn, it is wasteful to

devote time and energy to learn tasks that are too difficult or impossible. In an abstract sense, on an admittedly different task, our simulations show the ability to capture results like those in two new experiments on learning in human infants. Infants spend more time learning artificial grammars that are possible to learn than they do on grammars that are impossible to learn (Gerken, et al., 2011). Similarly, our neural networks abandon learning impossible tasks, but not tasks that are possible to learn. Further, the network results show that the more difficult the task, the earlier that learning is abandoned, a finding that could serve as a prediction for new human experiments.

Figure 7. Mean output epochs (with SE bars) for 20 networks, with learning threshold of .30.

Another infant experiment showed a Goldilocks effect in the sense of spending more learning effort on problems of moderate difficulty than on problems that are too easy or too difficult (Kidd, et al., 2010). Our networks show this effect as well, but add a qualification that the Goldilocks effect diminishes at higher levels of a learning-threshold parameter. This offers another prediction to test in human experiments. The psychological equivalent of learning threshold could be sensitivity to changes in error.

In our model, easy tasks are discarded because they have been learned, whereas overly difficult tasks are abandoned because learning has stalled. This identifies two different explanations for turning away from a learning task, one based on success and the other on failure. In contrast, learning may continue as long as some detectable progress is being made.

Our model offers a plausible neural mechanism for such phenomena that allows for further theoretical exploration and extensions. We plan to apply our algorithm to alternate tasks and problems, including those used in psychology experiments and those that vary on dimensions of difficulty other than the proportion of random training patterns.

Our model predicts that learners need to have learning experience with a problem in order to determine whether to continue with it or not. At least with inexperienced learners, there is no shortcut to avoid actually trying to learn. Supporting this idea, we found that amount of first-trial error does not predict learnability on the problems we studied here. Learners may need to give it a serious try

before being able to predict whether they might succeed. It would be interesting to see if this is also true of biological learners. If learners exhibit shortcuts to avoid attempted learning, this would imply generalizing across learning content due to previous experience, as when learning shuts down in the presence of mathematical equations.

We also found that overtraining effects can be eliminated with high learning thresholds. This is more realistic for autonomous agents than is monitoring error increases on a validation set of test patterns. Moreover, we find that the Goldilocks and overtraining effects tend to occur in the same circumstances, at relatively low rather than high learning thresholds. Goldilocks peaks are due to the increased learning times caused by low learning thresholds.

There is, of course, more to autonomous learning than abandoning unsuccessful learning. There is also, for example, the choice of which problems to try to learn. We hypothesize that novelty detection, characterized by high initial error, plays a role in choosing learning problems. Abandoning fruitless learning is an essential component of autonomous learning because, as noted, it frees the learner to search for and work on more appropriate problems.

## Achieving Autonomy in Learning

Our results show that a small extension to SDCC can provide a useful mechanism for detecting lack of progress in learning, which is an essential component of autonomous learning. In this context, it is worth considering how CANNs such as SDCC fare in terms of other aspects of autonomous learning (Douglas & Sejnowski, 2007). Although there are no completely autonomous artificial learning creatures yet, it is also true that CANNs have made considerable progress in increasing autonomy in learning.

In terms of network construction, SDCC, unlike algorithms for human-designed networks, autonomously designs and builds a network topology that is well suited to the problem being learned. The emerging topology can be flat or deep or anything in between, and learning stops when the problem has been mastered.

Unlike the ordered hierarchies of some static network topologies, SDCC implements a potentially deep, heterarchical topology in which increasingly higher-level, more abstract concepts are composed of simpler ones. Each new hidden unit in SDCC receives signals from input units and any existing lower level hidden units, thus continually building on existing knowledge. Knowledge-representation analysis shows that the first hidden units learn to represent the most obvious and superficial aspects of a problem domain, whereas later hidden units refine and abstract that knowledge (Shultz, 2003). This componential structure is further enhanced in knowledge-based CC (KBCC), where whole, previously learned sub-networks compete to be recruited (Shultz & Rivest, 2001; Shultz, Rivest, Egri, Thivierge, & Dandurand, 2007).

With regard to data selection, like many other artificial neural networks, SDCC focuses on inputs that predict its output, quickly ignoring inputs that are not predictive.

Although such non-predictive inputs are rarely included in practice, it is important to note that, when they are included, they are rapidly and functionally eliminated by learning of near-zero connection weights. It would be feasible to eliminate such detected irrelevant inputs from training patterns altogether, effectively allowing learning to focus attention on what is important while creating a more efficient network.

Among the issues that remain challenges for CAANs, as well as for other network learning algorithms, are single-trial learning, temporal spacing effects, the wake-sleep cycle, synaptic meta-plasticity, relations between brain structure and function, real-time learning in a changing world, and social learning (Douglas & Sejnowski, 2007).

The role of supervision of learning is a complex topic deserving more extended discussion than we can provide here. Suffice it to say that CANNs can learn without a teacher.

For more genuine and more complete autonomy in learning, we believe that it will be important to examine the evolution of learning methods and to implement computational models in robots, with pressures for real-time behavior in fluid environments. Evolution through natural selection is the most plausible natural source of learning mechanisms in both biological and artificial agents (Dunlap & Stephens, 2009). Based on the cost-benefit analysis we presented in the Introduction, it might be possible to show that abandonment of learning itself is favored by natural selection in evolution simulations. And, of course, robotic applications pose a particularly challenging test of learning autonomy.

## Acknowledgements

This research was supported by the Natural Sciences and Engineering Research Council of Canada, with an operating grant to TRS and a fellowship to FD. Planning this work benefitted from discussions with LouAnn Gerken, Nick Chater, and Scott Fahlman. We are also grateful to Vincent Berthiaume for relevant pilot work, Simon Reader for pointers to papers on evolution and learning, and Caitlin Mouri for helpful comments on an earlier draft.

# Listening to Thematic Music Prior to a Generation Task Causes Thematic Elements to Be Included in a Story Generation Task.

## Abstract

The current study examines whether thematic music (e.g., battle music) can activate related concepts in memory (e.g., weapons, death) and whether the activated concepts are more likely to be included in a story generation task. Participants listened to one of two 90-sec excerpts of thematic music (Baby theme or War theme) either before or after engaging in a story generation task. Their stories were examined to determine the degree to which the thematic elements of the music were included in the stories. Across two experiments, there was evidence that listening to war or baby themed music before engaging in a generation task increased the likelihood that elements associated with that theme would be incorporated into the story. Evidence also existed that the music theme interacted with the story theme to influence the degree that thematic elements would be incorporated into the story.

**Keywords:** concepts; categories; knowledge representation; music; creativity; generation.

## Introduction

We use music to celebrate events, entertain, motivate and inspire us. Hearing a song can bring back memories of a college romance. The musical score of a movie warns us when something unpleasant is about to happen. Given the pervasiveness of music in our lives, surprisingly little research has been directed at determining whether music is represented in semantic memory and how the musical associations stored in semantic memory affect performance on a variety of tasks

People's musical knowledge develops throughout their lives via exposure to such things as lullabies, music education, background music in television and film, and musical entertainment. Because people live in a musically rich environment, they become attune to the complexities of musical structure at an early age. Even three-year-old children demonstrate an understanding of the relationship between music in a major key being associated with a happy mood and music in a minor key being associated with a sad mood (Kastner & Crowder, 1990). This type of knowledge affects five to six-year-old children's interpretation of a story such that "happy" music playing in the background causes the children to form positive interpretations of a neutral story whereas "sad" music playing in the

background causes them to form negative interpretations (Ziv & Goshen, 2006).

Exposure to certain types of music becomes associated with particular events throughout a lifetime of musical experiences (e.g., weddings, circuses). It stands to reason that the link between music and event becomes strong enough that knowledge of the music will join object and event information in the concepts and schemas with which it is associated (e.g., "wedding music," "circus music"). Empirically demonstrating the existence of these associations is just beginning though.

Daltrozzo and Schön (2009) argued that music conveys concepts in the same way that images and words convey concepts. They supported this claim by demonstrating a larger N400 component of the event-related brain potentials to 1-second musical excerpt targets following a conceptually unrelated compared to a conceptually related linguistic context. Though this is fairly direct evidence of conceptual processing of musical information, it is left to other researchers to explain how such a short excerpt of music carries enough information to activate conceptual information in memory. Stronger (albeit indirect) evidence for the conceptual representation and processing of musical information is provided by North, Hargreaves, & McKendrick (1997) who demonstrated that ethnic background music can affect consumer decisions. When French music was playing in a wine shop, consumers were more likely to buy French wine than German wine. When German music was playing, the opposite was true, Boltz (2001) also demonstrated the effect of music on actions by demonstrating that musical soundtracks could activate a schematic framework thus affecting the interpretation of an ambiguous movie scene. Boltz (2001) had participants watch an ambiguous scene paired with either "positive" or "negative" music. She found that when a scene was paired with positive music it activated a positive schema resulting in positive interpretations of the events occurring in the scene (e.g., the man following the woman is a long lost lover) and subsequent memory for positive objects (e.g., flower bouquet) and events in the scene. When a scene was paired with negative music it activated a negative schema resulting in negative interpretations of the events occurring in the scene (e.g., the man following the woman is her brother and plans to kill her) and subsequent memory for

negative objects (e.g., human skull) and events in the scene. An interesting component of the paradigm Boltz (2001) used to demonstrate music acting as a schematic influence on the cognitive processing of film events is that she had participants extrapolate the film's ending as a means of examining the effect of schema activation by looking for elements of those schemas in the extrapolations. In demonstrating the influence of the schemas activated by the music via the events and objects described in participant's extrapolations of the film's ending, Boltz (2001) also demonstrated that music can activate conceptual knowledge which then affects performance in a generation task.

Those studying creative cognition, frequently use generation tasks to examine the influences of concepts and categories on performance. In doing so, they gain knowledge about the contents and organization of conceptual knowledge and how this knowledge is applied when generating new ideas. For example, Marsh, Binks and Hicks (1999) demonstrated that participants shown examples sharing the conceptual feature of hostility (e.g., weapons, fangs) were more likely than those not experiencing the examples, to generate novel exemplars with hostile features. They also demonstrated that simply activating the concept of hostility was sufficient to influence performance on a generation task. Participants who unscrambled hostile sentences were more likely to generate novel exemplars with hostile features compared to participants who had unscrambled conceptually neutral sentences.

If people represent thematic music in memory and that representation is linked to the objects and activities with which it is associated, it should be possible to activate that representation and its associated concepts by having people listen to the music. For example, if the concept of "war" is associated with a certain type of music, then having people listen to "war music" should activate the war concept and the elements associated with war such as "marching" and "weapons." Once those concepts are activated, they should affect performance in a subsequent generation task by increasing the likelihood that conceptual elements will be incorporated into the novel product.

## Experiment 1

As discussed, music experienced during goal-directed activity (shopping, watching a movie) has the ability to affect purchasing decisions as well as story interpretation and generation in what appears to be a conceptually congruent fashion. What is less clear is whether our representation of thematic music is rich enough that listening to such music in the absence of other stimuli is sufficient to activate more complex concepts such "fighting in a war" and "tucking a baby into bed" much less instantiate those concepts in a generation task. The current experiment seeks to demonstrate the ability of music to activate complex concepts in memory and affect the content incorporated into stories generated in a story generation task.

Participants will listen to one of two types of thematic music ("tucking a baby into bed" (baby) theme, "going off to war" (war) theme) either before or after a story generation task. The stories generated by participants will be examined for the presence of elements associated with either one of the two music themes.

We hypothesize that participants who listen to the war themed music prior to engaging in the generation task will include more war themed concepts than baby themed concepts in their stories than people who listened to the war themed music after engaging in the generation task. Participants who listen to the baby themed music prior to engaging in the generation task will include more baby themed concepts than war themed concepts in their stories than people who listened to the war themed music after engaging in the generation task.

## Methods

### Pilot Testing

**Participants, Stimuli and Procedure.** Thirty-one Oakland University students participated in exchange for experimental credit in the song-rating task.

Participants wearing headphones were seated at a computer and interacted with a Flash program that provided instructions, randomized song presentation and collected participants' responses to the songs. The 14 songs presented to participants during pilot testing satisfied the criteria of 1) being strongly thematic and containing at least 90 seconds of music devoid of 2) environmental sounds (e.g., barking dog, crying baby) or 3) lyrics.

On each trial, participants listened to a 90 sec. song clip, then listed the "first three things the song made them think of" and rated the familiarity, pleasantness, and liking of the song on a 7 point Likert scale (7 = most familiar, pleasant, liked) (See Table 1).

Responses to each song were content analyzed to identify the three most salient concepts (listed by > 30% of sample) that each song brought to mind (MusicConcepts).

The two songs chosen for use (DeLaTerra and Carousel) were selected because they 1) both elicited consistent thematic responses from participants ("war" and "baby" respectively), 2) the themes were extremely different from each other and 3) the songs were equally unfamiliar.

It was thought that the activation of a concept by listening to the music might spread to associated concepts and affect performance on the generation task. Consequently, a different group of 18 students enrolled in a Cognitive Psychology course engaged in a feature listing task, listing features for the three Carousel and three DeLaTerra MusicConcepts. Nine conceptually related features (MusicAssociates) were listed by at least 33% of the students in response to the Carousel MusicConcepts and seven features were listed by at least 33% of the students in response to the DeLaTerra MusicConcepts.

participant.

## Stimuli and Procedure

Participants were seated at a computer with headphones on and interacted with a Flash program in the browser that provided instructions, presented stimuli and recorded participants' responses. All participants spent four minutes engaged in a nine-item Remote Associates Task (included to disguise the study's purpose), listened to 90 seconds of music, and spent 15 minutes writing a story with the theme "My Adventure on an Alien Planet." Conditions different only in terms of which of the two songs participants experienced and whether the songs were presented immediately before or immediately after the story generation task.

## Coding

Raters blind to condition coded the stories generated by the participants for the presence of the MusicConcepts and MusicAssociates associated with the two songs. This resulted in four dependent variables: the proportion of Baby MusicConcepts, the proportion of Baby MusicAssociates, the proportion of War MusicConcepts, and the proportion of War MusicAssociates included in the story written by the

## Results

Four 2 X 2 ANOVAs were conducted examining the effects of music theme (Baby, War) and position (Before, After) on the proportion of MusicConcepts and MusicAssociates included in the stories.

The analyses revealed no main effects or interactions on the tendency for participants to include the Baby MusicConcepts or MusicAssociates in their stories,  $p > .05$ . The same was also true for the tendency to include War MusicConcepts in their stories. However, there was a significant main effect of position on the proportion of War MusicAssociates incorporated into the story,  $F(1, 137) = 4.34$ ,  $p < .05$ ,  $\eta^2 = .032$ . This main effect was moderated by a non-reliable interaction,  $F(1, 137) = 3.15$ ,  $p < .10$ ,  $\eta^2 = .023$ . Participants exposed to the War theme music before the story generation task included a greater proportion of War MusicAssociates into their stories ( $M = .04$ ,  $SE = .01$ ) than those who were exposed to War music after the generation task ( $M = .00$ ,  $SE = .01$ ) or those who were exposed to the Baby music either before ( $M = .02$ ,  $SE = .01$ ) or after ( $M = .02$ ,  $SE = .01$ ) the generation task.

Table 1: Characteristics of 90-second Song Samples and Evoked Concepts (Concepts)

Theme	Music		Music Primes	Familiarity		Pleasantness		Liking	
	Song	Artist		M	SD	M	SD	M	SD
Church	Dante's Prayer	Loreena McKinnett	Church, Sadness, Peace	3.4	1.77	4.75	2.01	4.34	1.81
Evil	Toccatta and Fugue in D Minor	Bach	Church, Organ, Horror	4.91	1.85	3.91	1.72	3.89	1.86

## Discussion

The hypothesis that thematic music experienced prior to engaging in a story generation task increases the likelihood thematic elements associated with that music will be incorporated into the story is partially supported. Participants exposed to music that brings to mind concepts associated with fighting in a war are more likely to incorporate concepts such as weapons, death and blood into the stories they write immediately after listening to the music. However, exposure to war themed music did not increase their tendency to incorporate the specific terms brought to mind by the music (as revealed in pilot testing) into their stories. Exposure to baby themed music did not appear to affect whether or not concepts associated with tucking a baby into bed were included in the stories either.

So why did exposure to war themed music affect performance and exposure to baby themed music did not? Perhaps because baby themed elements were incorporated into the stories at higher rates than war themed elements across all conditions. Specifically, baby themed elements related to sleeping and dreaming were commonly included in the stories generated by participants.

We believe participants faced with the task of describing their “adventure on an alien planet” seemed compelled to explain how they ended up on that alien planet. A common solution was to say they fell asleep in bed and dreamt that they were on an alien planet. If this is a valid explanation for the lack of influence of baby themed music on performance in a generation task, then perhaps a more plausible setting will decrease the use of literary devices such as sleeping and dreaming in the story generation task.

## Experiment 2

Experiment 2 tests the proposal that the story generation task scenario given to participants in Experiment 1 hid the influence of baby themed music by causing them to incorporate items associated with that theme (sleeping, dreaming, bed) into their stories to rationalize being on an alien planet.

We predict that providing a more “down-to-earth” scenario will allow the effects of the baby themed music to be manifested in the story generation tasks by decreasing the inclusion of the specific baby-themed concepts of sleeping and dreaming across all conditions as a literary device. We maintain the hypotheses that experiencing war themed music prior to engaging in a story generation task will increase the proportion of war themed items included in the story compared to when the music is experienced after the generation task. Similarly, experiencing baby themed music prior to the generation task will increase the proportion of baby themed items included in the story compared to when the music is experienced after the generation task or compared to when war themed music is experienced prior to the generation task.

## Methods

### Participants

One-hundred and seventeen Oakland University students participated in exchange for experimental credit and were randomly assigned to one of four conditions: 29 listened to Carousel before generation (Baby Before), 33 after generation (Baby After), 28 participants listened to DeLaTerra before generation (War Before) and 27 after generation (War After). None of the participants provided data for Experiment 1.

### Stimuli and Procedure

The stimuli and procedure were identical to Experiment 1 with the exception that participants were now asked to spend 15 minutes writing a story with the theme “An Adventure to a Foreign, Undiscovered, yet Inhabited Land.”

## Results

Four 2 X 2 ANOVAs were conducted examining the effects of music theme (Baby, War) and position (Before, After) on the proportion of MusicConcepts and MusicAssociates included in the stories.

Analyses revealed a significant music theme X position interaction on the incorporation of Baby MusicConcepts incorporated into the story in the generation task,  $F(1, 117) = 5.41, p < .05, \eta^2 = .05$ . Participants exposed to the baby themed music prior to the generation task ( $M = .10, SE = .02$ ) were more likely to incorporate Baby MusicConcepts items into their stories than people who were exposed to the music after the generation task ( $M = .03, SE = .02$ ) or people who were exposed to the war themed music before the task ( $M = .02, SE = .02$ ). In fact, those exposed to the war themed music before the generation task were actually less likely to incorporate Baby MusicConcepts into their stories than those exposed to the war themed music after the generation task ( $M = .06, SE = .03$ ).

Further analyses revealed no main effects or interactions on the tendency for participants to include the Baby MusicAssociates, War MusicConcepts, or War MusicAssociates in their stories,  $p > .05$ . This suggests the effects of thematic music on incorporating thematic elements into the story is more complicated than simply being the effect of whether or not thematic music is heard prior to the generation task. It appears as if incorporating thematic concepts into a story depends on the types of concepts activated by the music AND the context of the story generation task. The disappearance of the effect of War themed music on the incorporation of War MusicAssociates suggests that those War MusicAssociates are more compatible with people’s understanding of the types of adventures that are possible on an alien planet than they are with adventures to an unexplored, yet inhibited foreign land.

To statistically examine the effects of story scenario on the tendency to include Baby or War themed elements in a

story generation task, we conducted post-hoc analyses comparing Experiments 2 results to those in Experiment 1. We believe this is a valid comparison because the two experiments differed only in terms of the theme participants were asked to write a story about. Also, participants were drawn from the same subject pool during the same year for both experiments.

Because we are interested in how the story theme interacts with the placement and the theme of the music to affect the tendency to incorporate Baby themed or War themed items into the story, we combined the Baby MusicConcepts and Baby MusicAssociates variables into a single variable (BabyAll) that measures the proportion of both Baby MusicConcepts and Baby MusicAssociates (12 items total) included in the story. The same was done for the War MusicConcepts and War MusicAssociates, resulting in WarAll (10 items total).

Table 2. Effects of Music Theme, Position and Story Theme on Proportion of Total Baby and War Items in Stories						
			Story Theme			
			Alien		Foreign	
BabyAll	Music	Position	M	SE	M	SE
	Baby	Before	.07	.01	.06	.01
		After	.07	.01	.03	.01
	War	Before	.07	.01	.04	.01
		After	.06	.01	.04	.02
WarAll	Baby	Before	.02	.01	.01	.01
		After	.02	.01	.02	.01
	War	Before	.04	.01	.01	.01
		After	.02	.00	.00	.00

A 2 X 2 X 2 ANOVA examined the effect of music theme (Baby, War), position (Before, After) and story theme (Alien, Foreign) on the inclusion of baby themed items and war themed items in the story generation task.

The analyses revealed a significant main effect of story theme on the inclusion of baby themed elements (BabyAll) in the story,  $F(1, 254) = 5.91, p < .05, \eta^2 = .02$ . Participants are more likely to include BabyAll items when writing a story with an alien theme ( $M = .07, SE = .01$ ) than when writing a story with a foreign land theme ( $M = .04, SE = .01$ ).

Analysis of the tendency to incorporate War themed elements (WarAll) in the generation task also revealed a significant main effect of story theme,  $F(1, 254) = 4.09, p < .05, \eta^2 = .02$ . Participants are more likely to include the WarAll items when writing a story with an alien theme ( $M = .02, SE = .00$ ) than when writing a story with a foreign land theme ( $M = .01, SE = .00$ ).

There was also a non-reliable Music Theme X Position interaction  $F(1, 254) = 2.87, p < .10, \eta^2 = .01$ . Participants are more likely to incorporate WarAll items into their stories when they hear war themed music before engaging in the generation task ( $M = .03, SE = .01$ ) compared to hearing it after the task ( $M = .01, SE = .01$ ) or hearing baby themed

music before ( $M = .02, SE = .01$ ) or after ( $M = .01, SE = .01$ ) the task.

## Discussion

The hypothesis that a story scenario set on Earth would allow the effect of listening to baby themed music on the inclusion of baby themed items in the generation task to be visible was supported. Participants who listened to baby themed music prior to engaging in a generation task, were more likely than those who listened to the music after writing their story to include items that pilot testing indicated were specifically activated by the baby themed music into their stories. The effect of listening to war themed music on performance in a generation task was weak enough that it was not visible in the Experiment 2 data. However, combining the Experiment 1 and 2 data provided enough power to demonstrate listening to war themed music rather than baby themed music before engaging in a generation task does increase the number of war themed components that are included in the generation task.

To explain the results of the Experiments 1 and 2, we would like to propose that the story scenario that participants were writing about interacts with the type of concept activated by the music to influence the degree to which participants incorporate thematic elements of the music into the story. For both story themes it was demonstrated that whether or not music concepts were incorporated into the story was influenced by the scenario for which they were writing the story with both baby themed music elements and war themed music elements being more likely to be incorporated into the novel stories when writing stories set on an alien planet. Interestingly, the reason why each set of elements was more likely to be incorporated differs between the two scenarios and themes.

Demonstrating an effect of listening to baby themed music on the tendency to include baby themed items into the story in Experiment 2 but not in Experiment 1 is probably due to participants feeling a need to rationalize the visit to the alien planet in Experiment 1 causing them to rely on the plot device of falling asleep and dreaming that they visited an alien land. This was evident in the fairly high rates of baby themed items across all four conditions in Experiment 1. Because sleep, dreams, and bed were all “tucking a baby into bed” themed items, the plot device washed out any effects that hearing the baby themed music might have had on the stories participants generated. The plot device was not necessary for stories about an adventure in an undiscovered foreign land so only the participants exposed to baby themed music prior to the generation task included baby themed elements into their story.

In contrast, the greater tendency to include war themed elements in the stories in Experiment 1 compared to Experiment 2 probably was due to the concept of war being more congruent or plausible with a visit to an alien planet than a visit to a foreign land. This suggests participants’ knowledge of alien planets and foreign lands is influencing

which thematic elements activated by the music get incorporated into the story or whether they are incorporated at all.

The proposal that the thematic elements activated by listening to thematic music interacts with the knowledge of the story scenario to affect performance in a generation task is consistent with some of the previous work on conceptual expansion and concept activation. Sifonis (1995) (as discussed in Ward, Smith & Finke, 1999) demonstrated that participants asked to describe a restaurant for a race of bird-like aliens integrate their category knowledge of birds with their schema of restaurants to generate a novel exemplar of “restaurants for bird-like aliens.” These novel restaurants retained some of the salient features of restaurants on Earth (e.g., having tables and serving food). However, in the process of replacing the human customer in the restaurant schema with birds in the context of an alien planet, the novel restaurants incorporated features of all three types of knowledge: restaurants, birds, alien planet (i.e., the customers sat on perches at tables and were served worm burgers but didn’t have to pay for their meals because the civilization had advanced beyond the need to exchange money for services). Perhaps the themes activated by the music are, in fact, activating a complex schema rather than just the individual concepts and their associates that participants reported during pilot testing. If this is the case, then the effects of the music on story generation might be more evident when looking for schematic elements associated with the theme (e.g., baby theme activating schema elements associated with children and parents and school).

Another explanation for a process underlying performance in the story generation task is that the specific scenario participants asked to generate stories for activates a specific form of the thematic element. Solomon and Barsalou (2001) have argued that properties associated with a concept are represented differently in different concepts. For example, the property of “red” is represented differently for “hair” and “wine” and “blood.” The dominant representation of the property at the time of retrieval varies on the basis of context as well as other factors. Consequently, the specific conceptual properties that are activated by the thematic music and incorporated into the generation task might depend on the story context/scenario of the generation task. If this is the case, then coding the stories for the features associated with the specific combination of music theme and story scenario (e.g., features of an “undiscovered foreign land in which there are a lot of babies”), should increase the ability to observe the effects of the thematic music on performance in the generation task.

Additional directions for future experiments include finding music that more strongly activates a particular theme. Using familiar rather than unfamiliar music should increase the effect of that music on the performance in the generation task over the low levels observed in the current study. Alternately, perhaps music associated with a

particular geographical region (e.g., Arabia, China) would be more likely to result in those features being included in a story about a visit to a distant land than music with a theme that is not geographical in nature.

In summary, the research described in this paper provides preliminary data suggesting that music can be associated with concepts and that listening to the music can activate those concepts and affect performance in a generation task. Because of the pervasiveness of music in our lives and its use to help enhance our performance, moods or thoughts, developing a greater understanding of the influence music has on those thoughts and behaviors will allow us to increase the manner in which music benefits us. It will also increase our understanding of how music is represented in memory and how that representation is manifested in performance,

## Acknowledgments

Special thanks to the students of my Advanced Experimental Design class, especially Stephanie Camarata, Angela Hasman and Caitlin Kleist for developing the initial ideas that resulted in this research. I would also like to thank Scott Niewinski, Emily Olthoff and Candice Lambert for data collection and coding. Reviewer number two also receives my thanks for their insightful and useful comments that helped me improve this abstract.

## Abstract

Using the perspective of situated cognition we studied how people interact with a physical map to help them navigate through an unfamiliar environment. The study used a mixture of cognitive ethnography and traditional experimental methods. We found that the difference between high and low performing navigators showed up in the speed they completed their task and also in the way they use maps. High performers plan routes using a survey method whereas low performers use a route strategy. We suggest that when people are given a task that does not match their cognitive style they try to transform the task to better suit their cognitive abilities and cognitive style.

**Keywords:** Map use, navigation, wayfinding, situated cognition, spatial cognition.

## Introduction

Interest in human spatial cognition and navigational capacity has a long history, ranging from the pioneering work of Siegel & White (1975) to contemporary contributions by Montello (1998; 2005) and Hegarty et al. (2002; 2006). Spatial cognition is concerned with how people represent space and navigate through it. (Montello, 2005). In the “classical” view, knowledge, from the perceived environment, is represented as a *cognitive map* (Tolman, 1948, Galotti, 2008). Siegel & White (1975) distinguished three types of knowledge involved in forming and using cognitive maps: i) *landmark knowledge*, ii) *route knowledge*, and iii) *survey knowledge*. Landmark knowledge is information about the particular features at a location. Route knowledge is information about specific pathways for moving from one location to another; it may be coded procedurally or declaratively. Survey knowledge is metric information about the relative location and estimated distances between landmarks, the very thing captured in a standard map, showing the location of all paths and features in a Euclidean plane. All this work investigates the representational architecture of *internal* spatial representations, focusing on questions such as whether cognitive maps are map-like in nature or more like nodes in a graph representation.

Lawton (1994; 1996) found that people tend to report using one either an *orientation strategy* or a *route strategy* when navigating, but not both. Orientation strategies are cognitive processes that use survey knowledge, the umbrella term for world-centric relations. When a subject thinks in an allocentric reference frame using global attributes of a terrain such as cardinal directions, and Euclidean positioning of landmarks, they are using orientation or *survey strategies* (Prestopnik & Roskos-Ewoldsen, 2000) for wayfinding. Route strategies, by contrast, are based on an egocentric frame of reference, where paths are defined as those throughways available from where the subject is at the moment.

Research on spatial knowledge acquisition and navigation has mostly been confined to strict laboratory settings and virtual environments (e.g. Allen, Kirasic, Dobson, Long, & Beck, 1996; Montello, 1993), or to environments where the subject is led along a fixed route in an urban area (Kato & Takeuchi, 2003). In these studies maps have been used primarily as a diagnostic tool to reveal the subject’s internal representation. For instance, a subject might be asked to sketch the route she followed, marking down all the landmarks she can recall. (Liben, 2010). Little or no attention has been paid to the actual practices of subjects when they use maps to navigate.

A map, if properly used, is an artifact that extends a person’s *survey knowledge* (Montello, Hegarty and Richardson 2004). It behaves in the same way as an internal map except that it is external. Because we interact with internal and external representations differently, however, it is worth examining in detail the diverse ways that people interact with maps. Do all subjects rotate maps? When, why? How do they gesture? Do they point on the map and then to the world? How often do they glance at a map? When?

To study the practices of map use we videoed subjects using a map of UCSD campus as they found their way from a starting location to a goal location. In the analysis we divided our subjects into two groups – route-based navigators, and survey-based navigators – using the well-known measures developed by Lawton (1994). We report here on our findings and offer an explanation of the results

in line with the ideas of situated, distributed and embodied cognition.

Clark (2008) has coined a term, or principle, to label this type of interaction in which epistemic actions (Kirsh & Maglio, 1994) can be incorporated – *The Principle of Ecological Assembly* (PEA). This principle states that “*the canny cognizer tends to recruit, on the spot, whatever mix of problem-solving resources will yield an acceptable result with a minimum of effort*” (Clark, 2008, p.13). But, given the existence of individual differences in cognitive styles, it is not obvious that “a minimum of effort” means the same thing for all people. A specific instance of this is the difference between persons who have a preference for a route strategy or a survey strategy. Another aim of the present work is to study how map use might differ between people depending on their preferred navigation strategies.

Since we are bridging or trying to relate two different research traditions, we address our research questions using a combination of the experimental methods traditionally used in research on navigation and wayfinding, with cognitive ethnography used in research on situated and distributed cognition.

## Method

The study was undertaken on the University of California, San Diego campus. UCSD is sufficiently complex and covers a large enough area to be challenging for most navigators unfamiliar with the campus. It can also be considered representative of an urbanized area.

17 participants were recruited using Craigslist, which is an online ad-service where ads can be placed for a fee. The participants were between 20 and 58 years,  $Mean = 32.1$  ( $SD = 13.23$ ), 8 female, 9 male; they were unfamiliar with the UCSD campus. To eliminate vision as a factor in performance they had to have 20/20 vision – with or without corrective lenses or glasses.

Participants were asked to find their way from a starting point to goal location. Three different start-goal pairs were used. These pairs were chosen and evaluated during a pilot study, where they were determined to be equally hard. Criteria for hardness were the number of salient landmarks, the density of buildings throughout the area, length (air distance), visual access. By using start-goal pairs that overlapped and crossed through the campus center, the environmental features and vistas were as equivalent as possible, leading us to infer they were equally complex.

## Materials

The materials used in this study included the official visitor map of the UCSD campus, which was handed to the participants and used throughout the navigation task.

Several recording tools were used, including the handheld video camera – Canon Vixia HG21 – and a head-mounted video camera – ContourHD 1300 LED 1080p Headcam – that captured the behavior of the participants. The motion pattern of the participants was recorded via a GPS – Victory Corp. Columbus V-900 Multifunction GPS data logger.

The Santa Barbara Sense of Direction Scale (SBSOD) was used to measure the participants’ sense of orientation, or the awareness of location or orientation. This instrument is a self-report measure which has been found to predict objective measures of these abilities, such as dead reckoning (Hegarty et al., 2002). This instrument has proved to be internally consistent and has sufficient test-retest reliability. The SBSOD is highly correlated with measures of spatial knowledge acquired from direct experience in the environment, and Hegarty et al. (2002) has shown that it is related to knowledge that involve orienting oneself within the environment.

The Wayfinding Strategy Scale (Lawton 1994) is a survey that measures to what extent a person depends on strategies relying on survey knowledge or route knowledge respectively. The survey contains 14 items of the sort of propositions that participants have to grade the degree of agreement along a 5-point Likert-type scale.

To measure dead reckoning a pointing task was used. At a number of places the participants were asked to point in the direction of an unseen landmark; a traditional compass was used to assess the participants’ error in this task.

## Procedure

The study itself was divided into two separate sessions. The first session was a pretest, where participants filled out electronic counterparts to the physical instances of SBSOD and the wayfinding strategy scale over the internet. The surveys could be completed at any time the participants wished from the moment of agreement of participation in the study to the day when the experiment session began. The questionnaire was filled out prior to the experiment session, which was of vital importance as to ensure validity. If it would have been completed after the experiment trial, there would have been a possible risk that participants took into account their recent navigational performance, and thus affecting the self-assessment.

On arriving for the second session, a consent form was filled out by each of the participants, a parking permit was paid for and given to them if needed, and they were then told to step into a car for transportation to another location. From this moment on, the experimental session had officially started and they were instructed to try to pay attention to where they are located in the world from that point onwards. The participant was dropped off at one of the marked drop-off locations where they were picked up by another experimenter. On site of the drop-off point the equipment was set-up, which included mounting the headcam on the participant and getting a stable GPS signal. The participant was then told to estimate and point into the direction of the meeting point, the experimenter then used the compass to derive the correct azimuth which was then communicated to the participant.

After having been given the correct direction, the participant was led non-linearly to the actual starting point of the navigation task. The starting point was located approximately 100 meters away, occluded from the drop-off

point. Another dead reckoning task was performed, where the participants were told to estimate and point into the direction of the *drop-off point* this time, after which it was time to initiate the primary task of the experiment session – the navigation task. At this point, the participants were given the campus map and told which building they were standing next to at the starting point. The participants were given time to find the building on the map, after which they were then told what destination they would be finding their way to. In similar manner, they were given time to locate the building on the map. Now, they were told to navigate to the destination by foot preferably using the shortest path. After any contingent questions and uncertainties had been mitigated, and after they had been instructed to try to verbalize their thoughts navigational strategies out loud, they were given the signal that it was OK for them to begin the navigation trial.

Throughout the navigation trial, the experimenters where filming the participants with the handheld camera while at the same time interviewing them according to a stipulated script, while given the freedom to *ad lib* when interesting observations were made. During the navigation task, the participant where given two instances of the dead reckoning-task where the azimuths were jotted down by the experimenter. Finally, when the participants reached their destination, they performed one last dead reckoning-task which concluded the navigation trial.

### Coding procedure

Three experimenters were coding the video material, and although no formal kappa value was calculated to establish the inter-rater reliability, the experimenters were trained simultaneously and looked at each other's code at the outset and very beginning of the coding to establish a consensus. The coders also consulted each other whenever any phenomenon raised any doubts concerning how to code it.

The coding scheme included a time stamp for each observation, a high level transcription of the think aloud

verbalizations, as well as gestures and other bodily actions such as body turns and visual references of the environment. Of specific interest was how participants interacted with the map. Thus, physical actions and manipulations of the map were pertinent to incorporate and code for in the coding schema, such as map rotations and folding of the map, in conjunction non-physical interactions with the map (e.g. coding for glances on the map), in order to reveal regularities of map use with respect to preferences of map interaction. In addition, gestures such as pointing on the map, or putting a thumb on the current location on the map, or running a finger across the map was coded for as well.

## Results

In the first part we will report on the quantitative measures used, to set the ground for the second part where we will present detailed observations of the use of the map as well as other orientation strategies used by our participants.

### Quantitative results

The results from the measures on The Wayfinding Strategy Scale, in the table called Orientation score, SBSOD score, dead reckoning error, number of map alignments and map consultation frequency, as measured by number of glances per hour, are presented in table 1 Note that the Orientation score test was introduced after the first 6 subjects participation.

All these three measures show considerable variation, SBOD from 34 to 94, navigation time from 14 to 58 minutes, and map consultation from 77 to 292 glances per hour, i.e. a ratio of approximately 4:1; the number of map alignments show an even higher variation, from 0 to 10.

There is a clear dependency between these measures. Dead reckoning error is negatively related to sense of direction as measured by SBSOD ( $r = -.43$ ,  $p < .05$ ), similar to results by Hegarty et al (2002). Also, as predicted, there

Table 1: Overview of results on performance measures and variables

Subject	Gender	Orientation Score	SBSOD-Score	# Map Alignments	Navigation Time	Dead Reck. Err.	Tot glances	Glances/hour
Subject 1	F	N/A	53	3	28	69	40	85,7
Subject 2	M	N/A	37	4	15	11	36	144

was a marginally significant negative correlation between SBSOD and map consultation frequency ( $r = -.52, p < .051$ ).

To investigate the existence of any potential difference between people who claim to use orientation strategies in contrast to people who primarily rely on route knowledge when engaged in navigation, a median split was performed on the sample on the orientation score, creating two groups here named. “Orienters” ( $n = 5, \bar{x} = 29.2, SD = 2.39$ ) and “Non-Orienters” ( $n = 5, \bar{x} = 22.4, SD = 1.67$ ). The difference between the two groups was significant  $t(8) = 5.22, p < .001$ .

It was noted above that the frequency of map use varied considerably between the participants, and that this was correlated with sense of direction. The question is then if the difference in map use is just a quantitative difference, or if there also is a qualitative difference in *how* the maps are used. One of the most obvious differences in how subjects use maps turns on alignment and registration: whether subjects prefer to leave the map in its native upright position determined by the orientation of labels, or do they rotate it so that the features on the map align with what they see. Using this criterion there is a clear difference in map use between the two groups. Map alignment frequency is significantly lower for Orienters ( $\bar{x} = 2$ ) than Non-Orienters ( $\bar{x} = 8.4$ ) ( $t(8) = 3.15, p < .01$ ).

To get a deeper understanding of map use differences we turn to a detailed analysis of the way subjects interact with maps and the various orientation strategies used.

## Navigation strategies

Our participants all make use of Siegel and White’s (1975) three basic kinds of navigation information, survey, path and landmarks. But they do not do so in the same way. They use different cognitive strategies within each of these broad categories. When they extract information outside of their preferred mode they try to transform that information into their preferred form. To highlight these differences, we present excerpts illustrating the strategies used by high and low performers as measured by their orientation score. In the present study, we did not note any significant differences between high and low performers in the use of landmarks. But there are differences in the use of survey and path information.

### Survey information strategy

As many authors have suggested, maps can be seen as an external form of survey knowledge. Our argument is that external representations still have to be interpreted and often a map user will physically interact with a map to facilitate interpretation. High and low performers interact differently.

Take the case of participant S24. He was a top performer on all the quantitative measures, one of two subjects who *never* rotated or aligned his map throughout the entire navigation task. S26 was the other. He kept his map in its canonical label reading position, that is fixed in a north-up position. Shortly after he began the task he was asked whether he has a particular strategy in mind. He answers:

*“I think so, I mean the idea is that I’m just gonna go right down here [pointing and tracing downwards along a depicted walkway on the map] and probably take a left on Voigt [traces with his finger to the right along Voigt Dr] and go south on Hopkins Lane (...)”*

In the video we see that S24 leaves the map in a north-up position and slightly tilts it for the experimenter to see the map. S24 runs his finger quickly down the map – that is, in a southerly direction – and then hastily makes a perpendicular turn with his finger and traces rightwards on the map while saying “*and probably take a left on Voigt*”. When he runs his finger southward on the map while simultaneously claiming that he will go “*down here*” his motion is in the same direction as he is. The map is egocentrically aligned. But when he runs his finger to the right (east) while saying “left”, however, he is breaking the egocentric view. Arguably S24 is making an inference based on an imagined egocentric perspective. He *imagines* himself, or rather *projects* (Kirsh, 2008) his future location ‘down there’ onto the external representation – the map – and quickly translates between egocentric and allocentric perspectives. What is striking about this particular incident is the ease and speed with which he performs this multi-layered action.

By comparison one of the low performers, S11, uses the map in a very different way. She frequently stopped throughout the navigation task to look at the map and subsequently tried to align the map to correspond to the surrounding environment in order to extract and assimilate information of where to go next. In the following excerpt, she has a vague idea of *where* she is, but she is not sure of her bearings in terms of cardinal directions and exactly where she should go.

*“...I’m trying to find that way. [pointing on the map] I’m gonna look at it upside down so I can see where I...then I know ‘cause we were on Voigt [Drive] before...”*

Her ambition is to walk south on Voigt, but she is uncertain about her bearings. She previously saw a sign for Voigt Drive and has a rough sense of her self-location. She then rotates the map to align it with her view in her current position. In contrast to S24, who showed an impressive management of directionality in the map and world, presumably through internal computation of the relation between world-centric and egocentric information, S11 is unable (or unwilling) to make these internal transformations and instead rotates the map, adapting the map artifact to fit her internal representations. This allows her to deduce whether she should go left or right on Voigt Drive, i.e. thinking in terms of a path strategy, instead of thinking about the world in survey knowledge manner.

### Route information strategy

Low-performers preferred to travel on straight roads and paths. Curving paths make it harder to keep track of one’s cardinal direction. They also avoided travelling on paths with high visual complexity – such as dense buildings. High visual complexity makes it harder to identify one’s

preferred landmarks on a map; the more buildings the more visual distractors. Again, high-performers had no such aversions. They are sufficiently proficient in using cardinal directions that they do not hesitate to use curved paths, or take opportunistic short-cuts that twist, even if this means going through dense buildings.

Subject 11 explained why she preferred to walk along a path that clearly diverted from the direction of the goal destination and optimal solution:

*"I could have weaved through [the buildings] but I think it would have taken me much longer (...) this is a straight way, so it's good, I can avoid going through all the cluster of buildings, it's less complex (...) I get lost very quickly, to me it's a lot easier to navigate than having to go through and around buildings..."*

S24 has the opposite attitude. In this excerpt, he is walking on a pre-planned path eastbound but suddenly decides to take another path:

*"I'm gonna head up this path, and I didn't go that way [pointing on the map on the original path he was supposed to take] because it was directly east, and this path kinda branches southeast, which is the direction we're going towards, so I figure I'd take that one."*

In contrast to S11, S24 never hesitated to take a diagonal path, as long as it was a shorter path. He seemed indifferent to visual complexity, taking routes that required navigating through buildings located at the very center of UCSD campus where several large commercial stores and buildings are located. The whole time he managed to stay oriented and solved the navigation task with the least glances to the map and nearly the least travel time. It seems that high performers can use the world better. They can find paths using cardinal directions as a grid, while low performers instead develop and use paths that will minimize the need to orient using cardinal directions.

### Transforming the information to suit the style

One way of describing the differences between high and low orienteers is that high orienteers think mostly in a world-centric manner whereas low orienteers think in a map-centric manner. For a high orienteer navigation involves keeping track of one's bearing. Because they have much better dead reckoning skills they always have a reasonable idea of where they are and where they have to go. When they look at a map it may be to see what is coming up next, but it is more likely to verify that they are where they think they are. They want to update their location relative to where they must go. They can do this by finding their location on the map in the orientation they have been holding it. They have no problem tracking themselves going south on a map facing north. They sense they are going south. They get too little cognitive saving from reorienting it to pay the price of the harder readability that comes from inverting labels.

Low orienteers, however, do their reasoning on the map. They orient the map so that it is aligned with their currently perceived view of the world. They put it in correspondence with the features that are in view so that they can then trace

where they must go on the map to reach the destination. Since the two, map and world are in alignment, they can then take their bearing straight off the map. They need to walk in the same direction in the world as the map. The two can be laid on top of each other. Straight paths are to be preferred because each revision of direction requires re-checking the map and that is a cognitive effort. The cognitive cost exceeds the physical cost of walking farther. Similarly, it is easier to avoid high feature areas, where buildings are close together, because the more visual clutter there is the harder it is to align the map since it requires checking more buildings and more angles.

### Strategy choice and performance

It may seem that low orienteers must be slower than good orienteers. Whereas in general this is true it is by means necessary. An efficient map-user can keep the map reasonably aligned by taking long straight paths. This saves them the cognitive effort of re-aligning the map, and it saves time too because realignment can be time-consuming. It is quite possible that the map-using time saved by taking a straight path more than compensates for longer distance.

An interesting case is S15, who has a very low score on the sense of direction test, but also has one of the shortest navigation times (15 min). S15 seems very aware of her preferences, as illustrated in the excerpt below.

*"I'm gonna go straight [pointing with her arm and hand in forward direction] and then straight [pointing with the same arm in an orthogonal direction to the left] (...) I don't like diagonals."*

When we look at S15's details we see that she glanced at the map 300 times, the most of any participant. But her glances were brief because she stayed on a map-aligned course. Given the straight line route she chose this meant that she could rotate the map just a few times (5).

If we assume that S15's performance is solid evidence that she is a good navigator then it does not follow that navigation ability always correlates with spatial ability. In previous work on navigation (Hegarty et al, 2006), navigation ability was found to correlate well with measures of spatial ability and with self-assessment of sense of direction. But the case of S15 illustrates that while this may be true in general there are outliers for whom it is not true. We hypothesize that people who know their own strengths and weaknesses in spatial understanding develop interactive strategies that compensate. They develop techniques for coordinating map use with route features to minimize time and cognitive effort.

### Discussion

The results presented here show that how maps are used differs between different people, depending on their navigation abilities. Navigators with a high orientation score, keep the map in the same upright position regardless of how well this matches their current view of the environment. They have no problem in mapping the view of the map to their current view of the environment using internal or mental transformations. Navigators with a low

orientation score, on the other hand, find mental transformations effortful, and instead prefer to externally manipulate the map to align it with their current view. These two also seem to differ in how they plan their route through the environment. Navigators with a low sense of direction prefer to walk along straight lines and in the open. Even though their paths are not the most direct, in effect requiring them to take detours, they still prefer them as long as they make the navigation task simpler. Navigators with a high sense of directions invariably prefer the shortest path even when that involves cutting across visually complex areas, following paths that wind. They even take opportunistic short-cuts on narrow pathways whenever they can.

Another way of looking at the difference between these two groups is that good navigators, comfortable with using a survey strategy have no problem using the terrain information in allocentric form, i.e. as a map. The other group is more comfortable with a route strategy, they tend not to use survey strategies and not surprisingly they prefer terrain information that is presented in egocentric form. They do this both by initially planning a simple route with no curves, and they manipulate the map to be able to read off bearing directly from the map without having to perform transformations from cardinal to egocentric direction.

The disparities between the two groups suggest that they confront their navigation task operate in different ways. Survey strategists have good sense of direction. They maintain a strong sense of where they came from and where they have to go. A map for them is a tool to help see the future but they consult it primarily to get confirmation that their sense of bearing is correct. The map is more for feedback than pure planning. Route strategists rely much more heavily on maps. They plan every step of their route on the map, and they make point wise decisions about where they are and where they must go next by orienting the map. It seems that route strategists do as much computation on the map as possible, whereas survey strategists do as much computation on their internal representation of the world.

## Abstract

The present study examined how students' working memory capacity influences learning from animations with or without guidance. We tested three different conditions: visual guidance, instructional guidance, and no guidance. The results show that especially visual guidance was perceived as being helpful for making references between narration and display of an animation. However, students without guidance outperformed both groups of students with guidance on a domain-specific knowledge test. A significant interaction between type of guidance and working memory capacity revealed that visual guidance impeded learning in students with high working memory capacity, whereas instructional guidance impeded learning in students with low working memory capacity. Our results suggest that working memory capacity is an important learner variable that should be taken into account to understand intervention effects and to customize learning environments to learners' needs.

**Keywords:** learning; working memory capacity; animation.

## Introduction

Animations can make unseen movements, interrelationships, and interdependencies or "difficult-to-see" particles and components in a system visible and thus accessible to comprehension. Animation can be defined as "a pictorial display that changes its structure or other properties over time and which triggers the perception of a continuous change" (Schnotz & Lowe, 2008, p. 304). This definition also pertains to dynamic visualizations, for example, presentations of how a technical device works or how a complex object is assembled. After a long line of research, nowadays there is no doubt that well-designed animations are helpful tools for fostering learning and transfer in different domains (Höffler & Leutner, 2007; Linn, Chang, Chiu, Zhang, & McElhaney, 2011).

Disadvantages of animations in the context of learning are grounded in their transitory and simultaneous nature. First, the presentation of entities in an animation is time-limited and subject to transience. This can hamper processing of important pieces of information, especially when the learner has not paid immediate attention to the relevant animated parts. Second, the simultaneity that characterizes one of animations' advantages for learning is potentially also a pitfall. When a series of events takes place at the same time, learners' limited capacities may be overwhelmed. Hence,

meaningful learning that requires learners to actively select and organize relevant information in order to integrate it into existing schemata in long-term memory can be impeded.

Motivated by possible disadvantages of animations, design factors have been proposed that aim at guiding learners' visual attention (Ayres & Paas, 2007). We tested two promising ways of fostering attention guidance to relevant information in animations, namely instructional guidance by giving verbal instruction prior to the presentation of the animation and visual guidance by blurring out irrelevant information in the animation. In addition, we investigated the influence of working memory (WM) capacity on learning from animations with these two types of attention guidance.

## Guidance in animations

### Instruction

Providing instructions on how to select and integrate information that is presented in different modes can have a positive effect on learners' attention allocation and, thus, on learning processes. Instructions can be given before rather than during the presentation of a certain learning environment in order to avoid interference with the display of the learning contents during the actual learning phase. On the other hand, processes of recalling and maintaining the instructions during learning may "bind" WM capacities.

In the context of multiple external representations, instructing learners on the functional relationships between representations can foster learning outcomes by guiding visual attention (Schwonke, Berthold, & Renkl, 2009). Gopher, Weil, and Siegel (1989) argue that mere prolonged exposure to a complex and dynamic task does not necessarily improve a learner's performance. Instead, a complex task should be decomposed into subcomponents, and the focus of attention should be changed according to these predefined subcomponents. Computer game players who received instructions to focus on single sub-tasks—for example, first ship control and then mine handling—outperformed players without any instructions to change their focus (Gopher et al., 1989). When following these instructions, "by a systematic manipulation of emphasis on different task subelements, subjects were led to explore a

wider range of attention strategies and improved their ability to cope with the high load of tasks” (Gopher, Weil, & Bareket, 1994, p. 389). Moreover, trainee pilots who first adopted strategies in attention allocation according to the emphasis change method in a computer game were better at actual piloting of an airplane than trainees who did not (Gopher et al., 1994). The emphasis change method works by way of external instructions prior to the learning phase. It is based on change of focus on components of a complex task and feedback (Gopher et al., 1989). However, it remains open whether such a method fosters only sensomotoric skills or also (meaningful) learning from animations.

### **Cueing**

Cueing and signaling to highlight key information offer a more apparent and invasive way of attention guidance (Ayres & Paas, 2007). In general, cueing “refers to the addition of design elements that direct the learner’s attention to important aspects of the learning material” (Plass, Homer, & Hayward, 2009, p. 39). Learners are not required to remember prior instructions. Cueing can be achieved by adding attention-directing objects such as arrows, circles, or colors to make relevant parts more noticeable. Another possibility is to reduce the luminance or the clarity of irrelevant parts in the visual display so that the important parts attract attention (“spotlight display”; Jarodzka et al., 2010). This technique makes animations less complex by directing learners’ attention to relevant information, thereby reducing the search space and freeing capacities for meaningful learning (De Koning, Tabbers, Rikers, & Paas, 2010; Mautone & Mayer, 2001). Whereas arrows and colors run the risk of delivering too much new information, a change of luminance or acuity creates a spotlight and may be perceived as less distractive. The latter methods minimize the visual display to the most important parts and events while preserving a holistic view. The advantages of cueing should fit especially the needs of learners with low WM capacity and those who are easily distracted by simultaneity.

In a study on learning a perceptual task (i.e., diagnosing seizures in infants), cueing was used to guide the learners’ visual attention in a tutorial video. A spotlight display was superior to a circle display that was supposed to direct attention and to a control condition without visual guidance (Jarodzka et al., 2010). In line with these results, De Koning, Tabbers, Rikers, and Paas (2007) reported encouraging findings on the superiority of cued animations over non-cued versions in terms of comprehension and transfer performance. Unfortunately, these results could not be replicated. Cueing in an animation on the cardiovascular system did not lead to better learning outcomes than non-cueing, although eye tracking data revealed that learners’ visual attention was guided more frequently to cued than non-cued contents (De Koning et al., 2010). In sum, it is unclear why learners do not always benefit from cueing, even when their attention was successfully directed to the

relevant regions in the animations. Considering learner variables such as WM capacity may help in providing adequate answers to this open question.

### **Working Memory in Multimedia Learning**

Learning and comprehension are dependent on learners’ ability to allocate and regulate attention. Before information can be stored in long-term memory it has to be processed in WM (Baddeley, 2003). Given the limited capacity of WM, only a small amount of the perceived information can be actively processed in order to acquire knowledge in the form of schemas. In their review, Schüler, Scheiter, and van Genuchten (2011) showed that WM capacity is a stable construct that affects the processing of static multimedia learning material such as texts and graphics. Because of its constraints, capacity likely plays a prominent role in learning from animations which can put high demands on learners.

Animations are often complemented by narrations. Consequently, in addition to information presented in visual mode (i.e. display) learners have to integrate information presented in auditory mode (i.e., narration). This leads to simultaneous demands on different components of WM. Auditory information is processed in WM’s phonological loop, while visual information from the animated visual display is processed in WM’s visuo-spatial sketchpad. Both types of information have to be temporarily stored and integrated in the episodic buffer (Baddeley, 2003).

WM measures reflect a domain-free ability to hold and process several information chunks “actively” while ignoring irrelevant information through the control of attention. This ability varies between individuals and influences the task performance. Hence, higher WM capacity facilitates not only processing of multiple information but also suppression of distracting information. Individuals with high WM capacity outperformed individuals with low WM capacity on visual selective attention tasks thanks to their flexibility in allocating their attention to visual stimuli (Bleckley, Durso, Crutchfield, Engle, & Khanna, 2003). The same results apply to the auditory channel. In a replication of the cocktail party phenomenon, individuals with low WM capacities detected their name in an irrelevant message more often than individuals with high WM capacities did, indicating that low WM individuals are more susceptible to distraction; at the same time, high WM individuals outperformed low WM individuals on a shadowing task (Conway, Cowan, & Bunting, 2001).

The results demonstrate that WM capacity is of vital significance in the process of attention allocation to visual and auditory information. Thus, WM capacity should have an influence on learning from animations. Furthermore, it is reasonable to assume that learners with different capacities may require different types of attention guidance for successful learning. By implication, learners with different levels of WM span may react differently to the same

instructional design, such as verbal instruction or visual guidance.

## Hypotheses

In our approach, we tested the effects of two types of guidance in an animation depicting the processes within a technical device (i.e., parabolic trough power plant system). We tested three conditions: a visual guidance group, who watched an animation with a clear spotlight on the relevant information while the visual clarity of irrelevant parts was reduced; an instructional guidance group, who received an instruction prior to the animation to make references between the narration and the visual display; and a no-guidance group, who did not receive any guidance on how to process the animation. We tested the following hypotheses:

- (1) As part of a manipulation check, we expected that subjectively perceived difficulty to make references between narration and visual display would be higher in the no-guidance group than in the groups with guidance.
- (2) With regard to the learning outcome, we expected the guidance groups to outperform the no-guidance group on a domain-specific posttest.
- (3) Besides a general effect (“main effect”) of WM capacity on the learning outcomes, we assumed an interaction between guidance and WM capacity. Participants with low WM capacity should benefit more from guidance than would participants with high WM capacity.

## Method

### Participants

The participants were  $N = 81$  (62 female) students from the University of Freiburg (age  $M = 22.14$ ,  $SD = 3.18$ ). Participants were randomly assigned to one of three conditions: visual guidance, instructional guidance, or no guidance. Each condition comprised of 27 participants.

### Materials

**Prior knowledge test** A pretest on prior knowledge of solar energy and the parabolic trough power plant system consisted of 30 items. Knowledge about technical devices entails being able to describe their structures, processes, and functions (Kalyuga & Hanham, 2011): Structures are the components an object consists of and their relationships; processes describe what happens in the system and how the device operates; functions characterize the purpose of the device and its sub-components and “provide” the answer to the question of what it is designed for. The prior knowledge test thus required participants to answer questions on solar energy in general but also on the structures, processes, and functions of the system (Cronbach’s  $\alpha = .79$ ).

**Learning performance** In our animation structures, processes, and functions were specified visually and

verbally by the visual presentation and narration. Hence, the posttest also comprised questions on the structures, processes and functions of the parabolic trough power plant. The learning outcome was assessed with 40 items. The overall reliability of the posttest was good (Cronbach’s  $\alpha = .90$ ).

**Test of WM capacity: Letter-Number Sequencing test (LNS)** WM span was assessed by the Letter-Number Sequencing test measuring especially the WM and attention span (adapted from the German version of the Wechsler Adult Intelligence Scale, WAIS-III; von Aster, Neubauer, & Horn, 2009). Participants listened to a sequence of letters and numbers (e.g., T-9-A-3) and reproduced them afterwards, but were asked to place the numbers in numerical order and the letters in alphabetical order, (e.g., 3-9-A-T). The level of complexity was defined by the number of elements, namely letters and numbers. The test started with two elements, and the level of complexity gradually increased by adding one element at a time up to a final sequence of eight elements. For each correctly announced sequence participants received one point. All points were summed up to a total score (between 0 and 21 points).

**Animation** The animation was colored and lasted about 5 minutes. It depicted how a parabolic trough power plant and its three cycles (i.e., oil cycle, water-steam cycle, and salt cycle) work. Each cycle is characterized by unique structures and serves a specific role in the conversion of solar energy to electric power. The solar radiation as well as the direction and flow of the different fluids in the system were animated.

Corresponding to our three conditions, we developed three versions of the animation. The visual guidance version included cueing by blurring out the cycles of the system that were not in the focus of the narration. In this way, a holistic view of the animation was preserved, while the relevant parts were made more salient by “spotlights.” The purpose of cueing was to visually guide participants’ attention through the animation and to assist them in making references between narration and the animated visual display. In the instructional guidance version, participants had to read an instruction prior to the animation on how to make references between the narration and the visual display. They were informed that several things would happen simultaneously and that it was thus crucial to follow the narration and map it to the animation. A third version involved no guidance at all, neither visual nor instructional.

### Procedure

Participants were tested in individual sessions approximately 60 minutes in length. After being explained the procedure, participants were asked to complete a short questionnaire on demographic data. They were then seated in front of a 22” computer monitor screen that was set at an operating distance of 60 to 80 cm. Next, prior knowledge was assessed and participants were asked to give subjective

evaluations of their knowledge about the system (ten-point Likert scale from 1 = no knowledge to 10 = very good knowledge). The assessment of WM capacity followed (Letter-Number Sequencing), after which participants watched the animation. They were then asked to rate their knowledge about the system once again (after watching the animation), and asked how difficult it was for them to map between the narration and the animated visual learning content, again on a ten-point Likert scale. Finally, learning performance was assessed by a domain-specific posttest.

## Results

First, we conducted a one-way ANOVA on the pretest. The conditions did not differ with respect to prior knowledge,  $F(2,78) = 0.00$ ,  $p = .998$ ,  $\eta^2 = .00$ . Before and after the animation, participants had to rate their knowledge about parabolic trough power plants. Participants in each condition showed a significant increase in their subjectively perceived knowledge about the system after having seen the animation (no guidance:  $M_{before} = 1.30$ ,  $SD_{before} = 0.87$ ;  $M_{after} = 6.12$ ,  $SD_{after} = 2.41$ ;  $t(25) = 9.81$ ,  $p < .001$ ,  $\eta^2 = .79$ ; instructional guidance:  $M_{before} = 1.26$ ,  $SD_{before} = 0.71$ ;  $M_{after} = 5.35$ ,  $SD_{after} = 2.45$ ;  $t(24) = 9.05$ ,  $p < .001$ ,  $\eta^2 = .77$ ; visual guidance:  $M_{before} = 1.44$ ,  $SD_{before} = 1.31$ ;  $M_{after} = 5.00$ ,  $SD_{after} = 2.74$ ;  $t(25) = 6.50$ ,  $p < .001$ ,  $\eta^2 = .62$ ). There were no differences between groups with respect to their perceived knowledge after watching the animation,  $F(2,74) = 1.73$ ,  $p = .184$ ,  $\eta^2 = .05$ .

As part of our manipulation check, participants were asked to rate how difficult it was to map between the visual display and the narration during the learning phase. Because the assumption of homogeneity of variance was violated, we conducted a Kruskal-Wallis test. The type of guidance (experimental condition) significantly affected the perceived difficulties in making references between visual display and narration,  $H(2)=7.57$ ,  $p = .021$ . Mann-Whitney tests were used to follow up this finding (Figure 1). There was no difference between the no-guidance group ( $M = 5.19$ ,  $SD = 2.47$ ) and instructional guidance group ( $M = 4.22$ ,  $SD = 1.93$ ;  $U = 282$ ,  $p = .149$ ,  $r = -.20$ ), but participants in the no-guidance group reported significantly more difficulties in making references than did participants in the visual guidance group ( $M = 3.48$ ,  $SD = 1.63$ ;  $U = 217$ ,  $p = .009$ ,  $r = -.35$ ).

Nor were there any differences in WM capacity (LNS) between the conditions,  $F(2,78) = 1.42$ ,  $p = .248$ ,  $\eta^2 = .035$ . Overall, WM capacity was positively correlated with the learning outcomes,  $r = .32$ ,  $p = .004$ . To test our next two hypotheses, we performed a general linear model in which we predicted learning outcomes by condition, WM capacity (as continuous variable), and the respective interaction term. Condition had a significant effect on learning outcomes,  $F(2,78) = 5.78$ ,  $p = .005$ ,  $\eta^2 = .133$ . Pairwise comparisons revealed a significant difference between the no-guidance group and the instructional group,  $p = .039$ , as well as between the no-guidance and the visual guidance group,  $p = .043$ . The no-guidance group (adjusted  $M = 26.20$ , 95% CI

[23.63, 28.78]) outperformed both the instructional guidance group (adjusted  $M = 21.54$ , 95% CI [18.95, 24.12]) and the visual guidance group (adjusted  $M = 21.48$ , 95% CI [18.77, 24.20]).

Figure 1: Perceived difficulties in referencing between visual display and narration (1 = none, 10 = many; 95% CI).

The effect of WM capacity on learning outcomes failed to reach statistical significance,  $F(2,78) = 3.73$ ,  $p = .057$ ,  $\eta^2 = .05$ . However, there was a significant interaction effect between WM capacity and type of guidance (experimental condition),  $F(2,78) = 5.24$ ,  $p = .007$ ,  $\eta^2 = .12$ . Students with low WM capacity were hindered by instructional guidance and students with high WM were hindered by visual guidance (Figure 2). Overall, no guidance was a good fit for learners with low as well as high WM span.

Figure 2: Interaction between working memory capacity (z-scores) and learning outcomes (%).

## Discussion

The present study tested whether learners benefited from guidance in an animation on how a technical device works, and whether different types of guidance led to different learning outcomes. Furthermore, it investigated the interaction between learners' WM capacity and type of guidance. Learners in all conditions indicated a significant increase in their knowledge after watching the animation. In accordance with our first hypothesis, the no-guidance group reported the highest level of difficulties with making

references between the visual display and the narration, followed by the instructional group and the visual group, who reported the fewest difficulties. Nevertheless, because only the difference between the no-guidance and visual guidance group was statistically significant, we consider our hypothesis only partially confirmed. Contrary to our expectations expressed in the second hypothesis, the no-guidance group outperformed both guidance groups on learning outcomes. Our third hypothesis was partially confirmed, given that WM capacity did affect learning from animations. In our experimental conditions, visual guidance had a detrimental effect on learners with high WM capacity, whereas instructional guidance had a detrimental effect on learners with low WM capacity. In general, the no-guidance group performed best, despite more perceived difficulties in making references. It follows that low WM learners benefited from no and visual guidance while high WM learners benefited from no and instructional guidance.

Contradicting conclusions drawn by Ayres and Paas (2007) that animations are more effective when key information is cued or signaled, our findings suggest that cueing does not necessarily have a positive effect on learning outcomes although it can reduce the level of perceived difficulties. Cueing as well as instruction aim at reducing cognitive load by directing learners to the relevant information in the learning content. Making references between different sources of information (auditory and visual) can be assumed to be an indicator of cognitive load. In this respect, visual guidance accomplished its purpose by synchronizing highlights on visual information with narration and hereby facilitating mapping. However, we assume that this might have led learners to invest less effort in active learning, after perceiving the content as (too) easy to comprehend. The framework of desirable difficulties offers an explanation as to why visual attention guidance does not always lead to better learning outcomes in the field of dynamic visualizations (De Koning et al., 2010): learners may be “lulled into a false sense of understanding” that makes them overestimate their understanding of the learning content (Linn et al., 2011, p. 239). Hence, an animation that is designed to make comprehension and processing subjectively too easy can mislead learners about the necessary effort. One might deduce from this that some degree of perceived difficulty can challenge learners and make them invest more effort in active learning processes. When learners perceive the stimulus as being more demanding, they may try to compensate for that by expending more effort in understanding the material (Salomon, 1984). Based on these findings, we propose that in order to promote active integration of learning materials, learners need to be given some challenges. More research is needed to find the balance between promoting effort and overload.

Another explanation for the poor performance of both guidance groups may be unfamiliarity with the chosen types of guidance. Blurring out the irrelevant parts can irritate learners. Visual guidance is an invasive form of alteration to

the original display. It restricts learners’ natural exploration behavior to the highlighted parts of the learning environment; spotlights expose only the parts that are important for the immediate moment. As a consequence, a deeper holistic integration of past and present information may be disrupted. Instructional guidance, on the other hand, is a less invasive type of support, at least with respect to the visual display. However, it requires learners to keep the instruction in mind while processing the animation. In light of limited WM capacities, learning processes and recall of instruction may conflict; especially learners with low WM capacity may suffer from this type of guidance. High WM learners, by contrast, may be able to follow the strategy they were instructed to apply while simultaneously blocking irrelevant and distracting information through the course of learning. Furthermore, guidance, whether invasive or not, can interfere with already established strategies and, thus, with self-regulatory processes. In contrast to the method of emphasis change (Gopher et al., 1989), we did not offer any feedback to our participants in the instructional guidance condition, neither on their performance nor on their attention allocation. As a suggestion for further research we propose a real-time feedback on learners’ eye movements.

Narration per se influences a learner’s attention. It can evoke expectations and provide knowledge directly prior to the processing of visual information. Consequently, prior expectations and knowledge can affect attention allocation to a visual display and influence the integration of new information (Kriz & Hegarty, 2007). Narration can therefore function as a top-down guidance of visual attention (Kriz & Hegarty, 2007; Lowe & Boucheix, 2008). Students in the no-guidance condition were guided by the narration but still had enough room to explore the whole display and thus integrate diverse information. In sum, the no-guidance condition seems to be a perfect fit for learners who can self-regulate their needs according to their resources, for example, their WM capacity and prior knowledge. At this point it should be stressed that our participants were students in a highly selective psychology program who already had thirteen successful years of school education and thus may be considered highly experienced in learning from multiple external representations and dynamic visualizations.

Based on our findings, we suggest that future multimedia research should place more emphasis on learner variables such as WM capacity to shed light on intervention effects of instructional designs. From our point of view, WM capacity could play a severe role in learning processes that could be comparable to the significance of prior knowledge in this context (Kalyuga, Ayres, Chandler, & Sweller, 2003).

## Acknowledgments

We thank our technical consultants and supporters: Adrian Skuballa for programming computer-standardized tests, Michael Kutz for bringing our storyboard to life, and Clara Pieck for giving our animation her professional voice. Furthermore, we thank our student assistants: Nicole

Dillner, Caroline Fortunski, and Sabina Panetta. This research was supported by the ScienceCampus Tübingen "Informational Environments" (Adaptable and Adaptive Multimedia Systems).

## Abstract

People often behave as if category members share an essence, and essentialising a category in this way promotes inductive inference. Although natural kind categories have been predominantly studied, some social categories are essentialised and here we consider the inductive potential of religion categories for children in Northern Ireland. We asked seven-, nine- and eleven-year olds in Catholic-maintained, State-controlled and Integrated schools to decide whether pairs of children shared a property. We manipulated the degree of shared membership in religion, gender and musical categories. Overall, religion was much more inductively potent than gender, although older children and children from the Catholic-maintained school were more likely to use additional information about other categories when evaluating inferences. These results suggest that religion categories are a powerful basis for inference even in children as young as seven-years, and that religion categories may be essentialised in Northern Ireland.

**Keywords:** Essentialism, inductive reasoning, category-based induction, cognitive development

## Introduction

One of the central functions of categories is to support inductive inference (see Murphy, 2004). For example, knowing that someone is a member of the Rotary Club may help us to predict their behavior on the basis of previous encounters with other members of that category. The strength of an inductive inference from one member of a category to another is, in part, determined by the degree to which the category is essentialised. Members of essentialised categories are believed to share an underlying, unobservable essence (Gelman, 2003; Medin & Ortony, 1989), which we often can't define, and so is sometimes thought of as a place holder (Medin & Ortony, 1989). Essentialised categories are assumed to have innate potential, fixed boundaries, deep causal properties, the capacity to be informative, and stable membership across

time (Demoulin, Leyens & Yzerbyt, 2006; Gelman, 2003). Essentialist reasoning has been found very early in childhood; preschoolers make category-based inferences even when perceptual similarity conflicts with category-membership (Gelman & Markman, 1986).

According to Gelman (2003) inductive inference is an indirect measure of essentialism; the more a category is essentialised, the greater inductive potential it will have. Although there is a very large social psychological literature on essentialised social categories (e.g. Haslam, Bastian, Bain & Kashima, 2006), there has been relatively little work on how we make inductive inferences from social categories. In this paper we will describe a large developmental study designed to investigate the inductive potential of religious categories in Northern Ireland.

## Essentialised Social Categories

Evidence is accumulating to suggest that children essentialise certain socially-constructed categories (Birnbaum et al., 2010; Deeb et al., 2011; Diesendruck & haLevi, 2006; Gil-White, 2001; Hirschfeld, 1995; Kinzler & Dautel, 2012; Rhodes & Gelman, 2009; Taylor et al, 2009). Perhaps of most relevance to our goal of investigating religion categories is previous work on race and ethnicity. The degree to which race categories are essentialised has been studied in a number of ways. For example, Deeb et al. (2011, Study 3) presented Arab and Jewish participants with a questionnaire designed to investigate children's essentialised beliefs about such categories, whereas Rhodes and Gelman (2009) asked children whether categorization decisions made by an alien, most of which were inconsistent with the participants' social categories, were correct. Kinzler and Dautel (2012) asked participants whether a target child's 'race' or the language they spoke was most likely to persist into adulthood.

Although different methodologies lead to different conclusions about the developmental trajectory of

essentialist beliefs about race categories, it is clear that culture plays a role. For example, Rhodes and Gelman (2009) observed an effect of whether adolescents were from a rural or an urban background on how likely they were to treat 'race' as a natural kind. Deeb et al. (2011) showed that although essentialist beliefs about race categories appear to recede by late childhood, culture and experience play a role in determining the age at which they first begin to wane. Kinzler & Dautel (2012) found that European-American children do not treat 'race' as more predictive than language until the age of 10; whereas 5 year old African-American children privilege 'race' over language.

Other studies have examined the inductive potency of race categories. For example, Hirschfeld (1995) showed that children as young as three found race categories more inductively powerful than occupation or body build categories. In a study conducted in Israel with Jewish and Arab children, Diesendruck and haLevi (2006) compared the inductive potential of personality traits and a variety of social categories including ethnicity and gender. They found that five-year-old children treated social categories as having more inductive potential than personality traits, while adults found personality traits more powerful. However, when the children and adults made inductive inferences based on social categories only, ethnicity had the greatest inductive potential for both groups. Birnbaum et al. (2010) showed that ethnicity categories (Arab vs. Jew) had the most inductive potential for religious Jewish children by age 5 and up until 11 years of age. Birnbaum et al's study also highlights the effect of culture as neither secular Jewish children nor Arab children showed the same effect.

## Religion Categories

In this study we examined the development of sensitivity to the religious categories, *Catholic* and *Protestant*, in Northern Ireland. We are by no means the first to study the psychological effects of the history of sectarian conflict between Catholics and Protestants in Northern Ireland (for a relevant reviews see Trew, 2004). However, a study of the inductive potency of religion categories in Northern Ireland has the potential to add significantly to our understanding of essentialised social categories. Most obviously, whereas there are visual cues to racial or gender category membership, there are no such cues for religion category membership in Northern Ireland. Gil-White (2001) has suggested that essentialised social categories possess visual cues to category membership. In seeking to establish that social categories for which there are no visual cues can be highly inductively potent, our work will be a test of that hypothesis.

In addition, given the link that has been found between essentialism and stereotyping, prejudice and negative intergroup relations (e.g. Haslam, Bastian, Bain & Kashima, 2006; Howell, Welkum & Dyck, 2011; Pauker et al, 2010; Prentice & Miller, 2007), any tendency to essentialise religion categories may have important social implications for individuals in Northern Irish society. A review by

Prentice and Miller (2007) highlighted how essentialist beliefs, such as innate potential, immutability of category membership, stability of category membership over time, and the belief that deep, hidden properties of a category give rise to its observable properties can lead individuals to stereotype another group, feel less inclined to attempt to cross category boundaries that are apparently immutable, and maintain prejudicial attitudes towards an outgroup. All of these consequences of essentialised thinking could be said to pertain in Northern Ireland, yet there has been no study of how religion-category-based reasoning develops.

## The Current Study

This study aimed to examine the inductive potential of religion categories for seven-, nine-, and eleven-year-old children in Northern Ireland. The lower age group has been selected because of findings that by six to seven years of age, *Catholic* and *Protestant*, are meaningful social labels for children (Trew, 2004). Our first concern was the extent to which children are prepared to base inferences about individuals on information about the social categories to which they belong, and how that tendency changes over development. However, we were also concerned with the effects of the environment on inference-making from religion categories. One obvious environmental difference between Northern Irish children is the kind of school that they attend as in Northern Ireland there are different types of school: state-controlled (often attended primarily by children from a Protestant background); Catholic-maintained (attended primarily by children from a Catholic background); and integrated (attended by children from both communities). So as to examine effects of educational environment on inferences, we included school type as a variable in the study.

On each trial of our task we showed participants a line drawing of a child said to be a member of two categories, for example a male Protestant. Next we told participants that the child possessed a blank property (e.g. likes to play a game called *badlage*), and asked them whether they thought another male Protestant, a male Catholic, a female Protestant, and a female Catholic would also possess the feature. Unlike standard triad tasks, our method does not force participants to choose between categories as the basis for an inference. Work on ethnic categories (Deeb et al, 2011) has shown that younger and older children spontaneously mention and remember information about ethnic categories or use them as the basis for inference. Accordingly, we predicted that to the extent that religion categories are essentialised, all of the children in this study would base inferences on religion category membership. Other work (Birnbaum et al, 2010) has shown that older children take additional information into account when making inferences. Accordingly, we predicted that with development, children would use the control categories in our task as an additional basis for inference. Because Deeb et al. (2011) found that children from integrated schools were more sensitive to ethnicity categories, we predicted

that children in such schools in Northern Ireland might show greater sensitivity to religion category somewhat earlier in development than children attending other schools.

## Method

**Participants** One hundred and thirty five (67 females and 68 males) primary school children in Northern Ireland participated. Participants were aged 6-7 (P3), 8-9 (P5) and 10-11 (P7). Participants were recruited from one integrated (33 children: 9 in P3; 10 in P5; 14 in P7); one state-controlled (45 children: 12 in P3; 11 in P5; 22 in P7); and one Catholic-maintained school (57 children: 18 in P3; 19 in P5; 20 in P7). Children were tested for ten minutes each in a quiet corner of the school.

**Design** The study had a 3 (School: Integrated; State-controlled; Catholic-maintained) x 3 (Year: P3; P5; P7) x 4 (Trial Type: both categories overlap; religion category only overlaps; other category only overlaps; no overlap) mixed design. Trial Type was manipulated within subjects, and school and year were between subject variables.

On each trial participants received information about two children's membership in two categories. In four trials the categories were religion and gender, in four others they were religion and musical instrument, and in a final four they were gender and musical instrument. There were two religion categories, Protestant and Catholic, two gender categories, male and female, and two musical instrument categories, piano player and guitarist. Trials were blocked by category pair and block order was counterbalanced.

**Materials** Each participant attempted 12 trials. A trial consisted of a base picture and a target picture. The same base picture was used for four target pictures. In one of the base pictures, information was presented about the religion and gender categories of the child. In another, information was presented about religion category and which musical instrument the child could play, and in the third base picture, information was presented about gender and musical instrument. The sets of four target pictures presented with each base depicted four different children who either shared memberships of the same two categories as the base child, shared membership of only one of the categories, or shared membership of neither category. Example pictures and trials are presented in Figure 1.

In all cases information about category membership was related orally when a picture was presented. Religion category membership was visually represented by a picture of a familiar Catholic or Protestant cathedral in Northern Ireland. Gender category was clearly discriminable from the pictures because of visual cues such as dress and hair length, and musical instrument category was depicted by the inclusion of a picture of a guitar or a piano. When gender was not varied in a trial, the child was presented in silhouette.

Three unfamiliar, novel properties were invented: 'likes to play a game called badlage'; 'knows how to use a mixtle';

'will go brooping at the weekend'. The same property was used for each of the trials associated with a particular base picture, and the order in which properties were mentioned was fixed. However, the order in which base pictures were presented was fully counter-balanced so that each property was presented with each base picture an equal number of times. We also varied the base pictures so that, for example, the base child defined by membership of a religion and a gender category was depicted equally often as a Catholic boy, a Catholic girl, a Protestant boy or a Protestant girl.

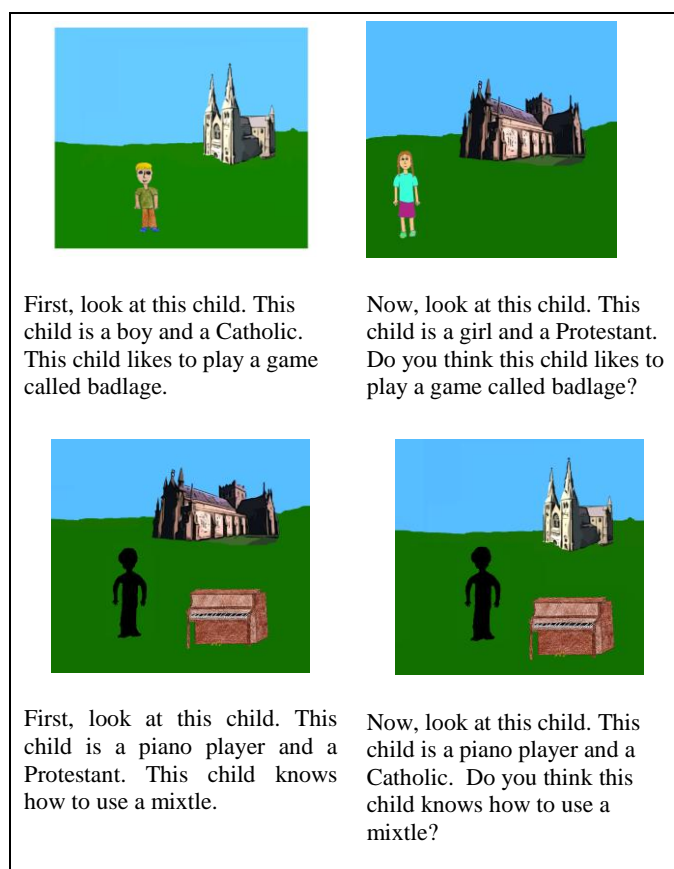

Figure 1: Example stimulus materials. The top panel illustrates how gender and religion categories were depicted. The bottom panel illustrates how religion and musical instrument categories were depicted.

**Procedure** Participants were tested individually at a quiet location in their school. On each trial participants indicated whether the novel property was possessed by both children or by the base child only.

## Results

We present a number of different analyses of our results. First, we present an analysis of the eight trials where information was presented about the religion category to which the base child belonged. In four of these trials, the other category was gender, and in the remaining four the other category was musical instrument. These eight trials

may be divided into four types. In two *REL+/GM+* trials, the base and target children belonged to the same two categories. In two *REL+/GM-* trials, base and target belonged to the same religion category, but to different gender or musical instrument categories. In two *REL-/GM+* trials, base and target belonged to different religion categories but to the same gender or musical instrument categories. Finally in two *REL-/GM-* trials, base and target belonged to entirely different categories.

We carried out a 4(Trial Type) x 3(Year) x 3(School) mixed design ANOVA on the number of times participants endorsed each type of inference. As may be seen in Figure 2, the results of this analysis contained a highly significant main effect of trial type,  $F(3, 378) = 56.38, p < .001$ . Post hoc tests revealed that each of the means involved in this effect differed significantly from every other mean. The main effect was qualified by significant interactions between School and Trial Type,  $F(6, 378) = 2.27, p < .05$ , and between Year and Trial Type,  $F(6, 378) = 2.46, p < .05$ . These interactions are shown in Figures 3 and 4 respectively.

Figure 2: Mean rates of inference for each trial type. (Note that here and throughout, bars marked with an asterisk differ significantly from chance.)

An examination of Figure 3 suggests that regardless of the type of school attended, children are more willing than not to project properties once the base and target children share religion category membership. However, only children attending the Catholic-maintained school were as willing to project properties in the *REL-/GM+* condition as in the *REL+/GM-* condition. These observations are supported by t-tests comparing the mean number of properties projected by children in each school on *REL+/GM-* and *REL-/GM+* trials. The difference was not significant for children attending the Catholic maintained school but was significant

for the other two groups of children. Thus, the finding here is of differences due to educational context in the potency of categories other than religion.

Examination of Figure 4 suggests that something similar underlies the significant interaction between Trial Type and Age. Whereas religion appears to be the only inductively potent category for seven- and nine-year-old children, eleven-year-olds are almost as likely to project the property in *REL-/GM+* trials as in *REL+/GM-* trials. The results of paired t-tests for each age group, comparing rates of

Figure 3: Interaction between school and trial type. (Bars marked with an asterisk differ significantly from chance.)

Figure 4: Interaction between year and trial type. (Bars marked with an asterisk differ significantly from chance.)

inference in each of these trial types, tended to support this interpretation. It is also apparent from Figure 3 that the oldest participants were more likely to project properties in REL-/GM- trials, but we have no explanation for this unexpected finding.

Thus far, we have collapsed gender and musical instrument categories together. It is clear from the analysis we have just described that overall, when information about religion category membership is present, religion categories are inductively more powerful than either musical instrument or gender categories. However, these analyses do not include trials where information about religion category was not present.

To examine the relative potency of all three types of category manipulated in this experiment, we calculated an index for each one reflecting the number of times a property was projected when there was overlap on that category type or relation. For example, the Gender index included G+/REL+, G+/REL-, G+/M+, and G+/M- trials. A 3(Relation) x 3(Year) x 3(School) mixed design ANOVA on scores on these indices revealed a highly significant main effect of Relation,  $F(2, 250) = 40.43$ ,  $p < .001$ , and a significant interaction between Relation and School,  $F(4, 250) = 3.05$ ,  $p < .02$ . The mean score on the Religion index ( $M = 3.00$ ) was just higher than the mean score on the Music index ( $M = 2.96$ ), but not significantly so. Both of these means were significantly higher than mean scores on the Gender index ( $M = 2.21$ ), and scores on all three indices were significantly greater than chance ( $p < .005$ ).

The interaction with School is displayed in Figure 5 where it appears that music is more inductively potent for children in the Catholic maintained school than is religion, whereas these two categories are equally potent for children in the Integrated school, and religion is more potent than music for

children in the State controlled school. A t-test confirmed that the difference between music and religion categories was statistically significant for children in the Catholic school. However, the difference between music and religion was not significant ( $p = .11$ ) for children in the State-controlled school. Scores on the Gender index were significantly lower than scores on both of the other indices for all three groups.

## Discussion

These results show that by age seven, children in Northern Ireland use religion categories—or at least the labels *Catholic* and *Protestant*—to guide inferences about non-obvious properties. These categories promote stronger inferences than other social categories (musicality, gender), and do so for children across a diverse range of school environments. Together, these findings suggest religion is essentialised by school children in Northern Ireland.

Although religion-based inferences were universal, we did see differences in the use of other social categories. Specifically, the musical instrument played by a child was a more potent guide for inferences for children in the Catholic school than the Integrated school, and more so for the Integrated school than the State school. Additionally, children in the State-controlled school were less likely than others to base inferences on gender. These findings suggest that culture or school may emphasize certain social categories over others, leading to differences in inductive potential for those categories. To children in Catholic-maintained schools, information about multiple social categories may be important, whereas to children in State-controlled schools, religion categories may be most salient. An alternative explanation is that ability levels differed between the schools, and that the use of information about more than one category to evaluate an inference requires additional cognitive resources. Further experimental work will need to be carried out in order to discriminate between these possibilities.

In addition to the universal potency of religion categories, we observed a developmental increase in the inductive potency of other social categories; 11-year-olds were more likely than younger children to base inferences on shared membership in non-religious categories. One interesting methodological point about the pattern of results that we have just described is that it would not have been detected by a standard triad task. To illustrate, Birnbaum et al. (2010) presented participants with trials where, for example, a child was said to belong to two social categories (e.g. a male Arab child) and participants were asked whether this base child was more likely to share a property with a male Jewish child or a female Arab child. Using this method, one can underestimate the age at which a certain type of social category begins to become important as well as the period for which it is important. Because our method did not force participants to choose between categories as a basis for their inference, we were able to observe that religion categories continued to be important at eleven-years of age but that

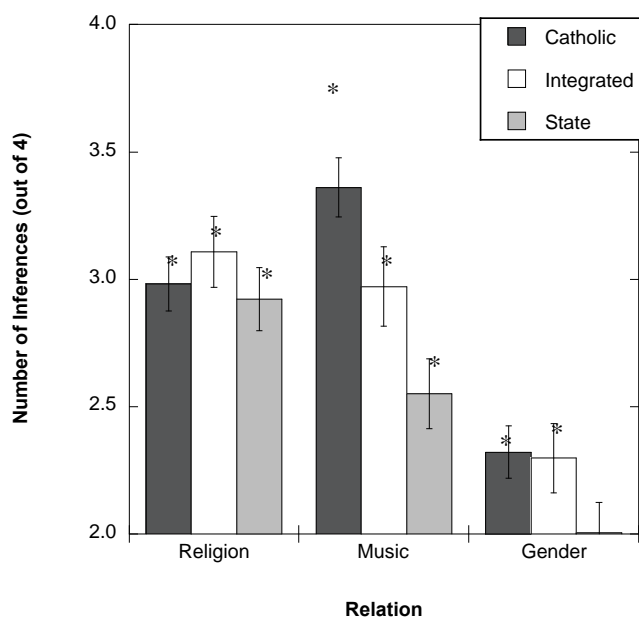

Figure 5: Interaction between Relation and school. (Bars marked with an asterisk differ significantly from chance).

other categories had also become more important by that age. Had we used a triad task we might have observed a tail-off in the apparent use of religion categories by older participants.

Of particular interest in this study is the performance of children from the Integrated school; by virtue of their contact with children from the “other” religious category they might display sensitivity to religion category earlier than children attending other schools. Deeb et al. (2011) reported such an effect for Jewish children attending integrated schools in Israel. We did not find an equivalent effect of school type here, although because we did not ask participants to disclose their religion, we cannot perform the same analysis as Deeb et al. (2011). Perhaps Catholic and Protestant children attending the same Integrated school behave differently, and we are currently carrying out a study designed, in part, to examine whether this is the case.

Consideration of children attending Integrated schools is useful when thinking about the relationship between a category’s inductive potency and the degree to which that category might be essentialised. One possible relationship is that social categories are inductively potent to the degree that they are essentialised, as argued by Gelman (2003). Another possibility is that a social category could be inductively strong even when it is not strongly essentialised. For example, Deeb et al (2011) reported a negative correlation between scores on a questionnaire designed to measure the extent to which children essentialise ethnic categories, and children’s tendency to recall information about ethnic category membership from an early description. Participants who essentialised ethnic categories less, recalled more information about ethnicity. This analysis collapsed across school type, so the result may have been driven entirely by children from the integrated sector. In any case, the result raises the possibility that children from different school sectors might perform similarly with respect to religion categories on an inductive inference task, but essentialise the categories to different extents. Members of a society divided on religious lines may not believe that members of the same religion category share an essence, but may still recognize the usefulness of information about religion category membership when making predictions about individuals.

Thus far, our work has concerned children growing up in a society that is still divided along religious lines. To properly assess the inductive potency of religion categories and the effects of culture on potency, there is a need for cross-cultural work comparing children in Northern Ireland to children from a society where religion is less divisive. For example, had we run this study in such a society we would have expected to find that gender categories are more inductively potent for children than are religion categories. We are currently collecting data to test this hypothesis.

We are at the beginning of a large project designed to investigate the extent to which religion categories support inferences differently across culture, across environment and across development. The results we have presented here

suggest that for children developing in a culture where religion categories are highly important, regardless of educational environment, those categories are inductively potent relatively early in development and continue to be so at least until late childhood.

## Abstract

Models of interference in sentence processing claim that object relative clauses are harder to process than subject relatives due to interference between the subject and object noun phrase. The interference effect for object relatives at the verb should be more pronounced when the two noun phrases retrieved from memory are similar. To test this, two eye tracking experiments manipulated whether the number feature of the noun phrases (singular or plural) was either the same or different. Both experiments showed the well-known relative clause effect. However, in Experiment 1 the effect of number congruency was in the opposite direction from that predicted by interference. Experiment 2 showed the interaction predicted by similarity based interference at sentence wrap-up, but because this interaction was observed later than the relative clause effect and only occurred in Experiment 2, it suggests that retrieval interference due to cue overlap is a weak effect that might be the result of a checking procedure in syntactically complex sentences.

**Keywords:** sentence processing; similarity based interference; working memory.

## Introduction

There is much evidence that object relative clauses such as (1) are more difficult to understand than subject relative clauses such as (2) (e.g., King & Just, 1991). It is generally believed that this difficulty stems from limitations in working memory (Gibson, 1998; Gordon, Hendrick, & Johnson, 2001; Lewis, 1996; King & Just, 1991).

1. The banker that the accountant helps counted the money.
2. The banker that helps the accountant counted the money.

For example, King and Just (1991) found that readers with low working memory experienced more difficulty with object than subject relatives. More recently, Lewis (1996) and Van Dyke and Lewis (2003) have proposed an account that assumes that working memory demands increase when two similar linguistic items (e.g., two noun phrases) need to be retrieved simultaneously, slowing down sentence processing. Lewis and Vasishth (2005) proposed an ACT-R account that explains how the processing of subject and object relatives is affected by the similarity of the noun phrases.

Consistent with this, Gordon, Hendrick, and Johnson (2001) found that object relatives are easier to process when the embedded noun phrase is a name (*Joe*) and the head noun a definite noun phrase (*the barber*) compared to when both are definite noun phrases.

However, Van Dyke and Lewis's (2003) and Lewis and Vasishth's (2005) similarity based interference account claims

that interference is not just due to similarity in the type of noun phrase but also due to similarity of other features. Van Dyke and Lewis (2003) described how the degree of overlap between a retrieval cue and two similar linguistic items affects the retrieval of these items. Two items (the subject and object noun phrase) have to be retained in memory in object relatives until they can be integrated with the verb. At the point of integration at the verb, retrieval cues are used to identify the target item from memory. When items in memory share retrieval cues it is difficult to identify this target. Thus, a similarity based interference effect arises for items with retrieval cue similarity. The account of Lewis and Vasishth (2005) predicts that a similarity based interference effect arises at the embedded verb in object relatives because two items have to be retrieved from memory instead of only one for subject relatives. This interference effect at the verb should be larger when these two items share retrieval cues.

For example, in object relatives like (1) the two subject and object noun phrases (*the accountant* and *the banker*) need to be simultaneously retrieved at the embedded verb (*helps*). On the other hand, only one noun phrase (*the banker*) needs to be accessed at the verb (*helps*) in subject relatives like (2). The similarity based interference effect that occurs with object relatives should be particularly strong when the two noun phrases that need to be retrieved are similar. Thus, because both the difficulty of object relatives and the difficulty of retrieving items that share retrieval cues are effects of interference at the embedded verb, they should occur at the same time.

Van Dyke and Lewis (2003) claim that number information is one of the retrieval cues for identifying a target. In relative clauses, congruency in the number feature of the subject and object noun phrase may have a strong effect on interference, because the subject has to agree in number with the verb: The retrieval cues of the target item (the subject noun phrase) have to match the number cue of the search probe (the verb). If the object has the same number as the subject and therefore also matches the number feature of the verb, this should result in interference when the subject and object are integrated with the verb. Thus, according to the retrieval cue based interference account, retrieval difficulty at the verb (e.g., *helps*) in object relatives should be more pronounced when the two noun phrases in memory share the same number than when they do not.

To test this account the current study investigated whether object relatives are harder to process when the two noun phrases in memory share the same number retrieval cue than when the number retrieval cues are different.

In sum, similarity-based interference models make the following three predictions for the experiments: (1) object relatives should be harder to process than subject relatives; (2) object relatives should be particularly hard to process when the subject and object noun phrase have the same number; (3) because both the relative clause and number effect predicted in (1) and (2) are due to interference when the noun phrases are retrieved at the verb (*helps*), the effects should occur simultaneously.

## Experiment 1

We conducted an eye movement reading experiment that contrasted sentences containing an embedded object relative clause with an embedded subject relative. The two initial noun phrases were either the same or different in number.

### Participants

Experiment 1 had 40 participants. All participants were non-dyslexic English native speakers and members of Dundee University. They received course credits in exchange for their participation. Participant treatment was in accordance with the ethical standards. The study was approved by the ethics committee at the University of Dundee.

### Materials and Design

Table 1 shows a sample item in all conditions and the areas of interest for the eye movement analyses. Thirty-two critical sentences were created in eight different conditions. The experiment had a 2x2x2 design with the factors (1) relative clause type (subject vs. object relative), (2) number congruency (subject and object noun phrases same vs. different in number) and (3) counterbalancing of number information (NP2 singular vs. plural). Because the number counterbalancing variable was not of theoretical interest, we collapsed across it in the analyses.

Eight lists were created. Each list contained 32 critical items, with four items in each of the eight conditions. One condition of each item appeared in each list. Five participants were randomly assigned to each list. In addition to the 32 experimental items, 85 filler sentences were presented and yes/no comprehension questions were presented after each sentence.

### Apparatus and Procedure

The experiment was carried out using the Experiment Builder Program from SR Research on a PC. An Eyelink 1000 Desktop Mount recorded participants eye movements at a 1000Hz sampling rate. The experiment was controlled by the Experiment Builder software on a separate PC. DataViewer (SR research) as well as R (R 2.13.1 foundation for statistical computing) were used for data analysis.

## Results

Three different eye-tracking measures were analysed for each region. *First pass duration* is the duration from entering an area of interest for the first time until leaving it into any direction. This measure does not include fixations that occurred after readers had fixated a subsequent region (i.e. the region of interest was skipped). *Regression path duration* is the sum of fixations from entering the area from the left for the first time until the first fixation outside to the right of the region occurs. That means that there should be no fixation on a right-bound region before entering the region in regression path duration. *Total reading time* is the sum of all fixations in an interest area.

Figure 1 shows regression path duration and total reading time in the different interest areas for Experiment 1. Since there were no differences between the conditions in first pass duration, we omit the plot for this measure here.

We conducted both analyses of variance with subjects (F1) and items (F2) as a random variable. Relative clause type and number congruency were treated as within subject and within item fixed variables. In addition, subject group was a fixed between subject variable in the by-subject analyses and item group a between item variable in the by-item analyses.

In the following results section we only report analyses of the variables that showed significant effects by subjects or by items.

**Critical Region (*helps the accountant*).** The analyses of variance showed a main effect of relative clause for regression path duration:  $F(1,32) = 33.03, p < .005$ ;  $F(1,24) = 35.09, p < .01$ . Reading times for object relatives were longer than for subject relatives. Total reading time at the critical region also showed an effect of relative clause:  $F(1,32) = 30.95, p < .01$ ;  $F(1,24) = 31.86, p < .01$ , indicating that object relatives took longer to read than subject relatives.

**Spillover 1 Region (*counted*).** Analyses of variance showed a main effect of relative clause type for the regression path duration measure,  $F(1,32) = 32.68, p < .01$ ;  $F(1,24) = 57.42, p < .01$ . Mean reading times for object relatives were longer than for subject relatives. The analyses also showed a main effect of number congruency for regression path duration:  $F(1,32) = 9.75, p < .01$ ;  $F(1,24) = 14.22, p < .01$ . Reading times were longer when the noun phrases were different than the same in number. The analyses of regression path duration also showed an interaction effect between relative clause type and number congruency,  $F(1,32) = 5.80, p < .05$ ;  $F(1,24) = 5.40, p < .05$ . Simple effect analyses for the object relatives showed that they took longer to read when the noun phrases were different than the same in number:  $F(1,32) = 8.94, p < .01$ ;  $F(1,24) = 12.22, p < .01$ . In contrast, simple effect analyses for subject relatives showed that there was no difference between the same and different conditions ( $F_s < 1$ ). For the total reading time measure, there was a main effect of relative clause type,  $F(1,32) = 25.11, p < .01$ ;  $F(1,24) = 15.87, p < .01$ . Reading times for object relatives were longer than for the subject relatives. In addi-

Regression Path Duration

Total Reading Time

Figure 1: Regression Path and Total Reading Times in Experiment 1

tion, the analyses of the total reading time measure indicated a marginal effect of number congruency,  $F(1,32) = 3.41$ ,  $p = .07$ ,  $F(1,24) = 2.96$ ,  $p = .09$ , with the different condition being read slower than the same condition.

**Spillover 2 Region (*the money*).** There were no effects in the spillover 2 region.

**Wrap-up Region (*several times*).** An analysis of variance of the regression path duration measure showed a main effect of relative clause type in the wrap-up region that was significant by subjects,  $F(1,32) = 7.01$ ,  $p < .05$ ; but not by items,  $F(2,24) = 4.18$ ,  $p = .05$ , with object relatives being slower than subject relatives.

## Discussion

Experiment 1 showed that object relatives were harder to process than subject relative clauses in regression path and total reading times for the critical region (*help the accountant*) and the spillover 1 region (*counted*). There was an effect of number congruency in total reading times in the spillover 1 region, with the different number conditions being harder than the same number conditions. A similar effect was also found in regression path duration in the same region, though it only occurred with object relatives. The direction of these congruency effects is opposite to that predicted by similarity based interference models, which claim that the same number condition should be more difficult. The reversed effect may be due to priming of number information from the first to the second noun. Most important, this suggests that similarity-based interference due to number congruency does not appear to have a strong effect on the processing of subject or object-relative clauses.

## Experiment 2

Experiment 1 showed an effect of relative clause type but no effect of number interference. It is possible that number interference does occur, but that in contrast to what is predicted by the similarity based interference account, it is a later effect. Number interference may occur after initial syntactic analysis of the relative clause, when readers check whether the verb also agrees with noun phrases other than the subject. This sort of mechanism is similar to the account put forward by Sturt (2003) for a delayed effect of *unaccessible antecedents* in anaphor resolution. Sturt (2003) argues that processes associated with this effect are not part of initial anaphor interpretation but later procedures like recovery and sentence wrap-up.

Because the region after the relative clause was relatively long in Experiment 1, the retrieval interference effect due to cue overlap may be spread out over the region and difficult to detect. Therefore, the final region after the relative clause was shortened in Experiment 2. The same materials as in Experiment 1 were tested without the final region (e.g., *several times*).

## Participants

The number of participants and the selection criteria for these participants were the same as in Experiment 1.

## Materials and Design

The materials in this experiment were the same as in Experiment (1) with one difference. Instead of two spillover regions and a wrap-up region after the critical region, there was only one spillover region followed by a sentence wrap-up region. Table 2 shows a sample item with the interest areas for this experiment.

## Apparatus and Procedure

The procedure and the apparatus were the same as in Experiment 1.

## Results

Figure 2 shows the plots for first pass duration and total reading time and Figure ?? the plot for regression path duration in the different interest areas. We analysed the results from first pass duration, regression path duration and total reading time in the same way as in Experiment 1.

**Critical Region (*helps the accountant*).** In regression path duration, we observed a main effect of relative clause type  $F(1,32) = 17.81$ ,  $p < .01$ ;  $F(1,24) = 16.91$ ,  $p < .01$ . Object relatives had longer reading times than subject relatives. The total reading time measure also showed a main effect of relative clause type,  $F(1,32) = 46.07$ ,  $p < .01$ ;  $F(1,24) = 31.80$ ,  $p < .01$ . Reading times for object relatives were longer than for subject relatives.

**Spillover Region (*counted*).** First pass duration showed a main effect of relative clause,  $F(1,32) = 8.95$ ,  $p < .01$ ;  $F(1,24) = 8.65$ ,  $p < .01$ : Object relatives took longer than subject relatives. In regression path duration, there was an effect of relative clause type that was significant by subjects  $F(1,32) = 6.23$ ,  $p < .05$  but marginal by items  $F(2,24) = 3.81$ ,  $p = .06$ . Analyses of total reading time for this region showed a significant main effect of relative clause  $F(1,32) = 39.00$ ,  $p < .01$ ;  $F(1,24) = 26.94$ ,  $p < .01$ . Mean reading times for object relatives were longer than for subject relatives.

**Sentence Wrap-Up region (*the money*).** In first pass duration, there was a marginal effect of relative clause by subjects:  $F(1,32) = 3.41$ ,  $p < .10$  but no effect by items  $F(2,24) = 1.97$ . There was also an effect of number congruency by subjects  $F(1,32) = 4.42$ ,  $p < .05$  but not by items  $F(2,24) = 2.51$ ,  $p < .15$ , with a longer first pass duration when the noun phrases shared the same number cue than when they did not. Most importantly, there was an interaction between relative clause type and number congruency in first pass duration  $F(1,32) = 4.10$ ,  $p = .05$ ; and  $F(1,24) = 4.91$ ,  $p < .05$ . Simple effect analyses for object relative clauses showed that they had longer reading times when the noun phrases were the same than different in number:  $F(1,32) = 6.20$ ,  $p < .05$ ;

Table 2: Areas of interest for the materials used in Experiment 2.

	critical	spillover	wrap-up

<i>Object relative</i>			
The banker(s) that	the accountant(s) help(s)	counted	the money.

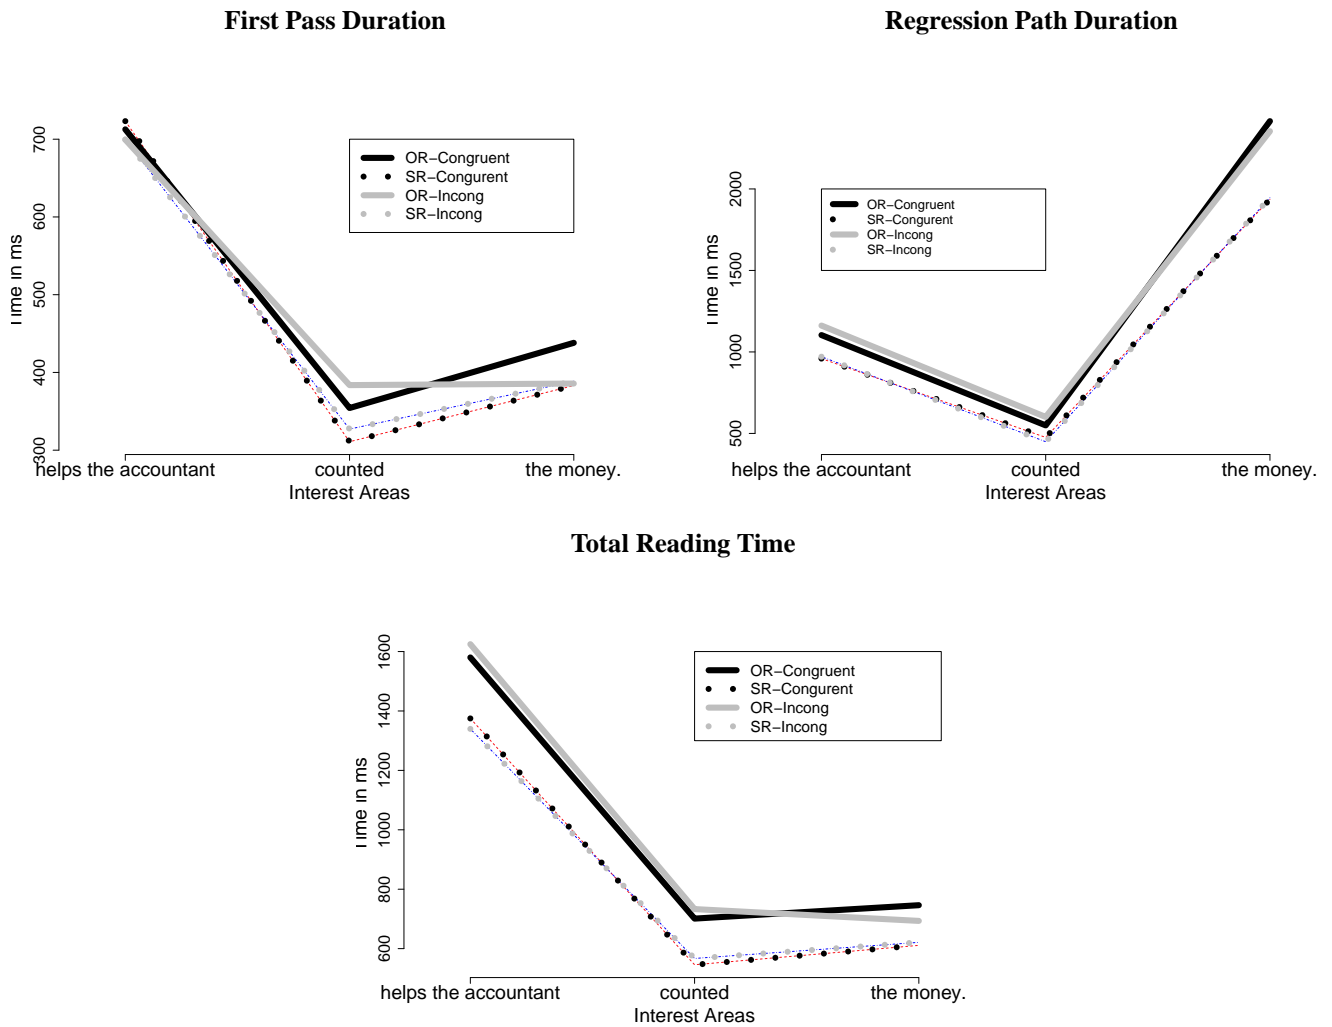

Figure 2: First Pass, Regression Path and Total Reading Times in Experiment 2

$F(1,24) = 5.97, p < .05$ . Simple effect analyses for subject relatives showed that there was no difference between the same and different noun phrases ( $F_s < 1$ ). The analyses of regression path duration showed a main effect of relative clause type  $F(1,32) = 22.76, p < .01$ ;  $F(1,24) = 10.70, p < .01$ . Object relatives had longer reading times than subject relatives. In the total reading time measure, we observed an effect of relative clause  $F(1,32) = 18.63, p < .01$ ;  $F(1,24) = 16.88, p < .01$ . Object relatives took longer to read than subject relatives.

## Discussion

Object relatives were more difficult than subject relatives relatives in regression path duration and total reading time (in all three regions) and in first pass duration (in the spillover region). Most interesting, there was an interaction between relative clause type and number congruency in first pass time for the final wrap-up region (*the money*): object relatives were more difficult when the noun phrases had the same number than a different number, whereas there was no difference for subject relatives. Thus, the number congruency effect appeared later than the object relative difficulty. This is surprising given the predictions made by the interference models mentioned in the introduction. Both the relative clause effect and the number congruency effect are claimed to be due to memory interference that occurs when the subject and object noun phrase are retrieved at the embedded verb. Thus, the difficulty with object relatives and the number interference effect should have occurred in the same regions and measures.

## General Discussion and Conclusion

Both Experiments 1 and 2 showed that object relatives are more difficult than subject relatives, which is in line with previous studies (Gibson, 1998; Gordon et al., 2001; Lewis, 1996; King & Just, 1991). This effect was found in the relative clause region (in regression path and total reading time in Experiment 1 and Experiment 2). However, neither Experiment 1 nor Experiment 2 found evidence for number interference in early measures. In Experiment 1, sentences were easier when the nouns had the same number than when their number was different. This is contrary to the predictions of similarity based interference accounts. In Experiment 2, there was evidence for number interference in object relatives, but this occurred during later processing, in the final region.

The observed delay of the number congruency effect in comparison to the relative clause effect in Experiment 2 is not consistent with memory interference models. They claim that difficulty with object relatives (compared to subject relatives) is due to interference that occurs when the subject and object noun phrase are retrieved at the embedded verb. Therefore, they predict that the number congruency effect should occur in the relative clause region, simultaneously with the slow-down with object relative clauses.

The results suggest that the interference effect is a later process that does not arise during structure building. One possibility is that it is due to a checking process that occurs

when a sentence is structurally complex as is the case with object relatives. Because this checking process occurs after the relative clause has been constructed, it may have been spread out over the regions following the relative clause in Experiment 1. Because the part of the sentence following the relative clause was long in Experiment 1, it may have been impossible to detect the later interference effect. When the main clause predicate was shortened in Experiment 2, we did find evidence for later number interference.

Together, the experiments suggest that the effect of retrieval cue overlap is weak. In addition to being weak, it occurs later than the relative clause effect, indicating that the initial difficulty with object relatives is not due to interference. These findings are more in agreement with theories that assume that processing difficulty with object relatives is not due to interference, such as the locality account (Gibson, 1998), experienced-based accounts (e.g., Wells, Christiansen, Rae, Acheson, & MacDonald, 2009) and expectation models (Levy, 2007; Hale, 2006).

## Abstract

Two experiments examined the hypothesis that constructing spatial representation and making inference from it with route description requires text continuity. Participants read the spatial text and answered true/false questions about it. In Experiment 1, we transposed sentences in a spatial text, and in Experiment 2, we inserted irrelevant tasks into a spatial text. The results showed that performance in a route perspective decreases when text has lost its continuity. This decrease in performance was not found in a survey perspective. These results indicate the continuous nature of route perspective, not only at the surface level of description but also at the level of cognitive processing.

**Keywords:** route perspective; survey perspective; spatial mental models, spatial representation, text continuity

## Introduction

When we think about a space or when we are trying to follow directions, we construct spatial representations and infer spatial information from them. Taylor & Tversky (1992) defined two types of perspective in the input and output of spatial representation—route perspective and survey perspective. In route perspective, terms such as “front,” “back,” “left,” and “right” are used to give directions from the perspective of an imagined viewer (e.g., “When you get out of the building, you can see a supermarket in front of you.”). Survey perspective, however, includes terms such as “north,” “south,” “east,” and “west” to give directions, taking a bird’s eye view (e.g., “The building is north of the supermarket.”).

Many studies have pointed out the difference between these two perspectives. Of specific importance to the present investigation, some studies (Pazzaglia & Cornoldi, 1999; Pazzaglia, Meneghetti, De Beni, & Gyselinck, 2010) focused on the two components of visuo-spatial working memory (VSWM) in route perspective. They divided VSWM into two components: the spatial sequential process and the spatial simultaneous process. Spatial sequential tasks require participants to recall the order of the stimulus

presentation, while spatial simultaneous tasks require participants to recall the visual configuration of the presented stimulus (Pazzaglia et al., 2010). Their results showed that the spatial sequential process is more involved in processing route description, whereas the spatial simultaneous process is more involved in processing survey description. This implies that the ability to process information sequentially is an essential factor for descriptions in route perspective.

More support for this idea comes from a study using children with learning disabilities (Mammarella, Meneghetti, Pazzaglia, Gitti, Gomez, & Colnoldi, 2009). Children with nonverbal (visuo-spatial) learning disability (NLD), reading disability (RD), or no disability participated in the experiment. They listened to route, survey, and non-spatial descriptions. After that, they performed a verification task and a location task. Although their performance was no different in the verification task with the non-spatial description, children with NLD showed decreased performance on the verification task, especially with regard to the survey description. In the location task, children with NLD had decreased performance more on the survey than on the route description (though this difference did not reach significance). Mammarella et al. (2009) showed that NLD children can form mental models from route description. They indicated that this is due to the “serial nature of language” involved in the route perspective.

Previous studies have shown the importance of spatial-sequential ability in route perspective processing. This ability belongs to the participants, and not to description itself. Therefore, in this study, we focused on the nature of description that whether each sentence had strong connections between itself and the previous/following sentence. There are two reasons why we emphasized continuity of route description. First, in route description, the directional terms are relative. Therefore, it is important to be aware of where one has come from and which direction he or she is facing. If no attention is given to it, one can easily get lost because the directional terms must be defined in relation with the imagined viewer. Second, the subject of the route description is “you.” In addition to

actually moving around, the subject of the description cannot warp to a distant place. They must move step by step, continuously.

In this study, we focused on the text continuity itself. Our hypothesis was that effective route description requires text continuity. If route perspective description is truly continuous, sentence order (i.e., text continuity) is important for it. In contrast, survey perspective does not need continuity and sentence order is less important. We manipulated the text continuity in two ways. In Experiment 1, we changed the order of sentences in a spatial text, while in Experiment 2, we inserted an interference task into a more complex spatial text. The novel point of this study is that we focused not on the traits of participants (Brunyé & Taylor, 2008b; Pazzaglia, et al., 2010), but on the traits of the text.

## Experiment 1

In Experiment 1, we tried to examine the effect of continuity of sentence order on comprehension of route description. Although previous studies (Pazzaglia & Cornoldi, 1999; Pazzaglia, et al., 2010) have shown the importance of the spatial-sequential ability of learners in processing route description, the effect of the sentence itself has not examined. If the processing of route perspective is actually continuous, a sentence in the description must be connected to the previous and following sentences. Therefore, when this connection is broken, one faces considerable trouble learning information from route descriptions. We did not expect this effect in survey learning, because survey perspective is simultaneous and not sequential (Pazzaglia et al., 2010).

## Method

**Participants** 35 Japanese graduates and undergraduates (19 males and 16 females) participated in Experiment 1 for a monetary reward. Mean age was 22.5 (range 18-28,  $SD = 2.6$ ). We excluded three males from the analysis for not following instructions. Half of the participants studied all descriptions in the survey perspective, and the rest in route perspective.

**Experiment design** The design was  $2 \times 2 \times 2$  with learning perspectives (survey vs. route) as a between subjects factor, text continuity (continuous vs. discontinuous), and test perspective (survey vs. route), as within subjects factors.

**Materials** Twenty-eight spatial texts were prepared. Each text consisted of four sentences and described one environment where four landmarks (landmarks A, B, C, and D) appeared along a straight road. The first sentence referred to the position of one landmark (landmark A) in relation to the road. The second sentence referred to the spatial relationship between landmarks A and B. The third

and fourth sentences referred to the relationships between landmarks B and C, and landmarks C and D, respectively. In discontinuous condition, the order of the third and fourth sentences was reversed. Therefore, the third and fourth sentences referred to the relationships between landmarks C and D, and landmarks B and C, respectively.

Each text had six verification tasks that asked about the relationships between two landmarks. Half were correct descriptions and the rest were incorrect.

**Procedure** We instructed participants to read the spatial text as fast as possible. After participants had finished reading the text, they answered true/false verification tasks about the environment that they had just learned about. Continuous and discontinuous texts were presented in random order. Halfway between the trials, participants took a rest. All stimuli were presented on a PC screen.

## Results

Trials that included reading time beyond  $\pm 2$  SD or under one second were excluded from the analysis below. According to this criterion, 77.7% of all trials were used.

Fig. 1 shows the accuracy of the verification question, which asked about the spatial relationships between the landmarks appearing in the third sentence. We chose only the third sentence because it is the initial sentence that differs according to the text continuity. In both continuous and discontinuous condition, the first and the second sentence are same.

The results of ANOVA showed a significant interaction ( $F(1, 30) = 4.997$ ,  $p = .03$ ,  $\eta_p^2 = .14$ ) between text continuity  $\times$  test perspective. All other interactions did not reach significance. In the survey test conditions, the accuracy did not show a significant difference ( $F(1, 30) = 1.400$ ,  $p = .25$ ,  $\eta_p^2 = .05$ ). In the route test conditions, however, the accuracy was higher in the continuous condition than the discontinuous condition ( $F(1, 30) = 4.608$ ,  $p = .04$ ,  $\eta_p^2 = .13$ ). In addition, the accuracy was higher in the route test condition than in the survey test condition when text was continuous ( $F(1, 30) = 10.343$ ,  $p = .00$ ,  $\eta_p^2 = .26$ ). This difference, however, was not found in the discontinuous condition ( $F(1, 30) = 0.146$ ,  $p = .70$ ,  $\eta_p^2 = .00$ ).

## Discussion

As we predicted, the accuracy was higher in the continuous condition than in the discontinuous condition when participants used route perspective during the test. In contrast, performance did not show significant difference between continuous condition and discontinuous condition when they used survey perspective during the test. These results show that participants need text continuity when they recall spatial representation in route perspective. When participants recall the spatial relationships, they rely onto spatial representations which they had constructed before.

And whether the construction of the spatial representation was continuous or discontinuous, affect the spatial

representation itself.

Fig. 1: Mean accuracy to the questions about the third sentence in Experiment 1 (bar means *SD*)

These differences however, appeared according to test perspective but did not according to learning perspective. This is not in line with our prediction. Although text continuity was a factor in learning, the performance differed according to the test perspective, rather than the learning perspective. We can think, however, that learning perspective has some effect on spatial representation. If spatial representations were the same regardless of learning perspectives, these differences would not appear because text continuity affects before the construction of spatial representation, not after. Therefore, constructed spatial representations should differ by the time participants construct it. One possible idea is that some factor lacks when participants learned the text in discontinuous conditions. They have to recall spatial information without the factor. When they recall in route perspective, the lack of the factor is make participants to have trouble in recall. When participants recall in survey perspective, however, the feature of survey perspective covers the lack of the factor. It is possible the factor is continuity of spatial representation.

One puzzling result is that participants showed better performance in route test than in the survey test when text was continuous. Previous studies showed superiority of survey perspective than route perspective in performance (Brunyé & Taylor, 2008a; Brunyé & Taylor, 2008b, Shelton & Gabrieli, 2002). We could not find this superiority of survey perspective in Experiment 1. There are two possibilities account for this tendency. One is that sentence order continuity works as a facilitator for route perspective, not that sentence order discontinuity works as an inference for route perspective. The other is that the studied

environments were too simple. It is possible that in a simple environment, participants need not to form abstract spatial representations, and it covers up the difference in learning perspective.

To solve these problems, in Experiment 2, participants studied a more complex text than that of Experiment 1. A complex text makes participants better infer spatial relationships according to their spatial representations. Therefore, the verification task would reflect their spatial performance more accurately.

## Experiment 2

In Experiment 2, as in Experiment 1, we examined the hypothesis that effective route description requires sentence continuity. We used the spatial texts used in Taylor & Tversky (1992). These texts were more complex than those used in Experiment 1, and participants had to make an inference about the environment. We manipulated text continuity by inserting irrelevant questions into the text. In the continuous condition we inserted short tasks that did not relate to the main text, yet still made participants conduct spatial inferences (such as “How many windows do you have in your room?” or “Which city is in the north, Kyoto or Nagoya?”). In the discontinuous condition, we inserted a simple counting task not to let participants rehearsal the text (“ $200 - 7 = ?$ ” or “ $100 + 8 = ?$ ”).

We made two predictions about the results. First, when participants learned the text from a survey perspective where the text did not need to be continuous, recall performance did not differ between the two conditions of

text continuity. However, when participants learned text from a route perspective where the text does need to be continuous, performance did differ between the two conditions.

## Method

**Participants** 67 Japanese graduates and undergraduates (34 males and 33 females) participated to Experiment 2 for a monetary reward. Mean age was 21.1 (range 18-25,  $SD = 1.8$ ). 33 participants (17 males and 16 females) studied all descriptions with a survey perspective, and 34 (17 males and 17 females) studied all with a route perspective.

**Experiment design** The design was  $2 \times 2 \times 2$  mixed, with learning perspectives (survey vs. route) as a between subjects factor, with text continuity (continuous vs. discontinuous) and test perspective (survey vs. route) as within subjects factors.

**Materials** Three tasks were conducted. Spatial text learning, Corsi blocks (Corsi, 1972) and the pathway span test (Mammarella, Cornoldi, Pazzaglia, Toso, Grimoldi, Vio, 2006). All tasks are conducted on the PC screen.

We used two spatial texts (town and convention center) from Taylor & Tversky (1992). Each text described an environment from two perspectives—survey and route. Each text had 28 True/False verifications: four questions were non-locative recognition, four were non-locative paraphrased, four were survey recognition, four were route recognition (survey and route recognition questions required inferences when study perspective and test perspective differed), six were survey inference, and six were route inference. In each category, three statements were true and the rest were false.

When participants learned the text, we inserted irrelevant tasks in every three sentences. In discontinuous condition as an experimental condition, we inserted spatial questions which are irrelevant to the main spatial text. Participants had to infer spatial relationships or to recall spatial alignment of objects which does not appear in the main text. We instructed participants to answer in five seconds. After five seconds passed, they return to the learning of the main text independently of the fact they answered to the inference questions or not, and the answer is correct or not.

In continuous condition as a control condition, we inserted simple counting tasks. We used counting tasks to prevent participants from rehearsal of the main spatial text. We instructed participants to repeat answering by five seconds passed (e.g. 93, 86, 79 ...). After the five seconds passed, they return to the learning of the main text.

In the Corsi blocks task, participants memorized the order of the position where a dot appeared. The number of stimuli in one trial was from four to seven, and there were twelve trials. This task measured spatial-sequential ability. Studies

have found positive relationships between this task and route perspective performance (Mammarella et al., 2006; Pazzaglia & Cornoldi, 1999; Pazzaglia, et al., 2010).

In the pathway span task, participants were told to follow movement in a five by five matrix according to the direction instructions. The number of instructions in one trial ranged from four to seven, with twelve trials in total. This task also measured spatial-sequential ability.

## Procedure

First, participants conducted the Corsi blocks task. Then they were allocated to either the survey study condition or the route study condition, as performance on the Corsi block task did not differ between conditions. Next, participants read two spatial texts. One text was read for the continuous conditions and the other for the discontinuous conditions. After they read one spatial text, they answered 28 true/false questions about each text. Finally, they conducted the pathway span test. All stimuli were presented on a PC screen.

## Results

One male was excluded from the analysis because he did not follow instructions. Another male was excluded because his verification performance in one condition was much lower (19.4%), although chance level was 50%. Both of them studied in the survey perspective. Verbatim questions that included reaction times beyond  $\pm 2$  SD were excluded from the analysis. According to this criterion, 97.0% of all trials were used.

Fig. 2 shows the accuracy of the verification task where participants needed spatial inferences. The results of the ANOVA showed a marginally significant interaction between text continuity  $\times$  test perspective ( $F(1, 65) = 3.769, p = .06, \eta_p^2 = .05$ ). In the continuous condition, the accuracy in survey and route condition did not showed significant difference ( $F(1, 65) = 0.219, p = .64, \eta_p^2 = .00$ ). In the discontinuous condition, participants showed lower accuracy in the route test than in the survey test ( $F(1, 65) = 5.614, p = .02, \eta_p^2 = .08$ ). In the survey test condition, the accuracy in the continuous condition and discontinuous condition did not showed significant difference ( $F(1, 65) = 0.663, p = .41, \eta_p^2 = .01$ ). In route test condition, participants showed lower performance in the discontinuous condition. The effect size of this difference is not small. This difference, however, did not reach to significance ( $F(1, 65) = 2.428, p = .12, \eta_p^2 = .04$ ). We conducted ANCOVA which controlled for the scores either Corsi blocks task or pathway span test or both of them. Those analyses, however, showed no statistical significance.

## Discussion

As predicted, when text lost its continuity, participants in the route test condition decreased performance compared to

requires text continuity was partially supported in Experiment 2. The discontinuous text lowered the accuracy

the survey condition. Our hypothesis that route description

when participants were tested in the route perspective. The

Fig. 2: Mean accuracy to the spatial inference questions in Experiment 2 (bar means *SD*)

effect was, however, limited and some predicted results did not reach to significant level.

As in the Experiment 1, the effect of text continuity appears according to the test perspective. We have a good reason, however, to believe text continuity affect how we learn the spatial information as we stated in the discussion of Experiment 1.

Previous research (Pazzaglia & Cornoldi, 1999; Pazzaglia, et al., 2010) has shown the importance of the spatial-sequential ability of learners in processing route description. This study shows that not only the spatial-sequential ability of the readers but also the text continuity itself is important to route description. This result reveals the more continuous nature of the route perspective than the survey perspective. In route description, it is clear that one must remember from where he or she has come, and which direction he or she is facing. The result of this study indicates that text continuity is essential, not only to description itself but also to the mental processing of route description.

## General Discussion

We conducted two experiments and examined the effect of text continuity in route perspective. In Experiment 1, we manipulated text continuity by transposing the sentences. In the test phase, text continuity increased performance of the route perspective. In Experiment 2, we manipulated the continuity by inserting irrelevant tasks into the more complex spatial descriptions than Experiment 1. Performance on the route test decreased in the discontinuous condition where participants inferred spatially. These results

support our hypothesis that route perspective needs text continuity.

Previous studies have found that spatial sequential ability is necessary for learning route description (Pazzaglia & Cornoldi, 1999; Pazzaglia, et al., 2010). In this study, we found that not only spatial-sequential ability but also text continuity is essential for understanding route descriptions. This dependence on continuity seems to relate to the nature of route description, as readers must continuously update changes in their local environment (Shelton & Gabrieli, 2002).

This study revealed that text continuity affects the retrieving of spatial information in route perspective. It remains unrevealed, however, when text continuity affect route perspective. There can be two possibilities about it. There was a significant interactions between test perspective  $\times$  text continuity. There is no doubt, therefore, text continuity affect at the test. In this case, spatial representation formed in discontinuous condition lacks continuity regardless of the learning perspective. When one uses route perspective to retrieve information from that discontinuous representation, a problem occurs. He or she can't rely onto continuity of the representation, has to navigate in his/her spatial representation discontinuously and the performance decreases. When one uses survey perspective at the test, whether the spatial representation is continuous or discontinuous does not matter. He or she can successfully retrieve information from his/her spatial representation even when it is discontinuous. Although the interaction between study perspective and text continuity was not statistically significant, this does not necessarily

denies the possibility of the effect of text continuity at learning. It is possible that the effect of text continuity at learning exists, however, is too weak to affect at the learning.

We refer to three remaining problems in this study. First, we used spatial text to present stimuli to participants in this study. Text and languages are naturally continuous and the results of this study might appear only when one studies one's environment using language. Therefore, we must confirm these results through other forms of studying, such as navigation in reality or watching videos involving specific locations. Second, we have to solve problems about the types of two inference tasks in Experiment 2. We regarded spatial question as an inference task and counting tasks as a control one. This distinction, however, is relatively arbitrary. It is possible that these tasks differed in types of inference, not in continuity. To solve this problem, we may need another control condition which is different from ones in continuity. In addition to that, forming spatial representation and extract information from that is quite complex process and are thought to be affected by individual difference. Participants take many strategies and their abilities differ quite a large way (Kato & Takeuchi, 2003). Therefore, it is possible that individual difference and strategy preference affect the results and covers up the effects of some factors. In Experiment 2, almost all results showed the same directions with the predictions. The statistical analysis, however, showed only few of them. Therefore, the next step is to take into account individual difference and the strategy preference.

## Abstract

Two experiments investigated the development of two aspects related to stress assignment in reading. First, we tested whether the role of distributional knowledge concerning stress changes with the development of the reading system; second, we tested whether stress information is computed independently of phonemic information since the first stages of reading acquisition. We ran two identical experiments in Italian, one with children of two age levels (second and fourth grades) and one with adults. Results showed that older children behave similarly to adults, but younger children do not. Differently from the advanced readers, younger children use more general distributional knowledge about stress and are not able to compute stress information apart from phonemes. Taken together, our results suggest that the stress subsystem, and in particular the mechanisms working at the level of the phonological buffer are not fully developed during the first stages of reading.

**Keywords:** lexical stress; stress neighborhood; reading development; pathway priming.

## Introduction

The process of stress assignment has recently become a central issue in the reading aloud literature. In languages like English, Dutch, or Italian, with a lexicon composed of polysyllabic words and with unpredictable stress, understanding how people read words aloud implies, among other things, understanding how readers assign stress. Research on stress assignment in reading has mainly focused on two issues: First, how readers assign stress to words and nonwords (*e.g.*, Colombo, 1992; Rastle &

Coltheart, 2000); Second, how suprasegmental information is represented in the reading system (Colombo & Zevin, 2009; Sulpizio, Job & Burani, in press b).

Let us consider the mechanisms for stress assignment first. Although stress assignment may not cause problems in reading words – readers may retrieve stress information as part of their lexical knowledge – it causes difficulties when stimuli are unknown words or nonwords. Thus, one issue is how readers are able to assign stress with no reference to lexically-stored information (Sulpizio, Arduino, Paizi, & Burani, in press a). Within a connectionist view of reading, studies in English and Italian have highlighted that two different types of distributional knowledge drive readers in stress assignment to unknown stimuli. First, the distribution of the stress patterns in the lexicon – *e.g.*, in Italian, 80% of three-syllabic words bear penultimate stress (maTIta<sup>1</sup>, pencil), while 18% bear antepenultimate stress (BIbita ‘drink’) (Thornton, Iacobini, & Burani, 1997)<sup>2</sup>. This may induce readers, following a default stress bias, to assign the most common pattern to unknown words (Colombo, 1992; Rastle & Coltheart, 2000). Second, some orthographic/phonological units work as cues for stress assignment, with word ending being a strong predictor of the stress pattern (*e.g.*, Arciuli, Monaghan, & Ševa, 2010; Kelly, Morris, & Verrechia, 1998). Consider Italian as an

<sup>1</sup> Capital letters indicate stressed syllable.

<sup>2</sup> The remaining 2% of three-syllabic words bear stress on the final syllable, and in this case stress is graphically marked (*e.g.*, colibri ‘hummingbird’)

example: Most of the words ending in -ola bear antepenultimate stress (PENTola, 'pot'; BAMbola, 'doll' *etc.*), that is, -ola has a stress neighborhood composed of many antepenultimate stress friends. Following this statistical tendency, when readers see an unknown word or a nonword ending in -ola, they will be prone to assign antepenultimate stress according to its stress neighborhood (Burani & Arduino, 2004; Colombo, 1992; Sulpizio *et al.*, in press a). Thus, readers have two sources of information to assign stress, *i.e.*, the lexical knowledge and the distributional information driven by their implicitly acquired statistical knowledge.

The representation of stress within the reading system has been investigated only recently. Two studies on Italian have shown that suprasegmental information may be partially independent from segmental information: Using a priming methodology, both studies found that the word's stress pattern can be primed independently of its segmental level (Colombo & Zevin, 2009; Sulpizio *et al.*, in press b). This finding is in line with the word production literature (Levelt, Roelofs, & Meyer, 1999) – where stress is part of an abstract metrical representation including the number of syllables and stress position – and with the view that speech production and reading aloud may share, at least in part, the last stages of processing, *i.e.*, phonological and phonetic word encoding (Roelofs, 2004). Thus, stress information would be partially independent of phonemic information and readers could compute the former independently from the latter.

But what about young readers? When a child starts to read, her/his reading system is not fully developed, her/his lexicon may be relatively small, and her/his knowledge of the statistical properties of the language may be relatively limited. How can the development of the stress system be characterized? Does knowledge of stress properties and its application to reading require time to develop? The issue concerning the development of distributional knowledge for stress has received little attention (but see Arciuli *et al.*, 2010, discussed below). To our knowledge, few studies investigated how a metrical representation, autonomous from segmental information, develops in young readers. Colombo, Deguchi and Boureux (submitted) found that young (7-years old) children were little affected by the stress pattern of the priming context nonwords in reading nonword targets, while priming was significant in older children.

In the present paper we further investigated the issue of whether children, when starting to read, are able to use the autonomous representation of stress as adult readers and thus may show stress priming effects. Differently from Colombo *et al.* (submitted), we used real words as targets. Words have a lexical representation which includes stress position. Consequently, if the words' stress pattern is retrieved from lexical memory, this information may be automatically available before information from the prime has any effect, particularly in children whose reading processes are relatively slow. On the other hand, Sulpizio *et*

*al.* (in press b) found significant stress priming for words in adults. Thus the question of whether and in which conditions we may find stress priming for words in adults and children is still open.

We ran two identical experiments, one with children of two age levels (II and IV grade) and one with adults. We adopted the "pathway priming" paradigm (Colombo & Zevin, 2009; Zevin & Balota, 2000) to test the possibility of inducing stress priming not only in adults, but also in young readers. In this paradigm, each target is preceded by five nonword primes with the same stress pattern that act as a small list context for the target. These micro-lists were included in a larger list in which all primes were homogeneous for stress. Participants have to read all stimuli aloud and they are not aware that some stimuli are primes and others are targets. By manipulating the congruency between primes' stress and target's stress – the target could have the same stress as the five preceding primes or a different one – we investigated whether a priming effect would occur, with participants being facilitated when reading a target in the congruent stress condition (when the target had the same stress as its five preceding primes), compared to the incongruent stress condition (when the target had a different stress than its five preceding primes). We expected that the stress priming effect would be stronger in adult readers and (perhaps) in older children, than in younger children.

Colombo and Zevin (2009) showed that stress priming effects are stronger within a sub-lexical context. Consequently, we only used nonwords as primes. In this way, participants were strongly encouraged to rely on sub-lexical reading. The use of nonword stimuli allowed us to further test the second issue: How readers develop distributional knowledge for stress assignment. Arciuli and colleagues (2010) ran a nonword reading experiment with English-speaking children. They found that younger (5/6-year-old) children were more affected by the main distribution of stress patterns in English – they assigned stress to the initial syllable more frequently – and were not affected by the final part of the nonwords. By contrast, in older children (7/8-year-old) the bias toward initial stress became weaker and children were influenced by specific orthographic cues, such as the nonwords' ending. A similar pattern of results was found in Italian. While young children were more prone to assign dominant stress to nonwords and less affected by orthographic neighborhood than older children and adults (Colombo *et al.*, submitted), Italian adults and older children (11 years old) assigned stress to nonwords and low-frequency words on the basis of stress neighborhood, showing very weak evidence for a bias toward the penultimate (dominant) stress in reading words aloud (see also Burani & Arduino, 2004; Colombo & Zevin, 2009; Paizi, Zoccolotti, & Burani, 2011). If these findings reflect cognitive constraints holding for different languages, we might expect similar trajectories in the development of distributional knowledge for stress in English and Italian: Older children and adults should be more affected by stress

neighborhood, while younger children might be more influenced by the distributional bias toward the dominant stress.

In summary, the present study investigated two issues related to the development of stress assignment in reading. First, we investigated whether stress assignment is fully developed already in young readers so that, when reading a word aloud, they are able to exploit the prosodic information available from the context. Second, we investigated whether the trajectory of the development of stress assignment in Italian is similar to what Arciuli *et al.* (2010) found for English, *i.e.*, that distributional knowledge of stress moves from a general distributional bias to more subtle statistical properties, such as stress neighborhood. To test these issues we ran two reading experiments in Italian, a language in which stress is not predictable by rule (Krämer, 2009) and there are two main stress patterns asymmetrically distributed, *i.e.*, penultimate stress – which is the dominant pattern and appears in 80% of words – and antepenultimate stress – which appears only in 18% of words. The two experiments were identical, except that one was run with children of different grades and one with adults.

## Methods

### Experiment 1 - Children

**Participants.** Two groups of elementary school children took part in the experiment: The first group included 20 second graders (13 males, mean age: 7.1, sd: 0.3); the second group included 18 fourth grade children (10 males, mean age: 9.2, sd: 0.4). All participants were native Italian speakers, with normal or corrected-to-normal vision.

**Materials & Method.** Thirty three-syllabic antepenultimate-stress words were used as target stimuli. All words had a low frequency (mean frequency: 15.93, sd: 27.96, out of 1.5 million occurrences, Barcelona Corpus, Istituto di Linguistica Computazionale, 1989, unpublished manuscript). The phonological lexical representation of low frequency words is less likely to be automatically retrieved, and thus priming should be easier to obtain. Two sets of three-syllabic phonologically legal Italian nonwords were used in order to create two stress priming contexts. They were constructed in such a way that one set should receive penultimate stress and the other one should receive antepenultimate stress according to the stress neighborhood consistency. Thus, nonwords having the nucleus of the penultimate syllable and the last syllable typical of words stressed with the penultimate (dominant) stress pattern (*e.g.*, -ato in geLAto, “ice cream”) were defined as penultimate-stress primes, whereas nonwords having the nucleus of the penultimate syllable and the last syllable typical of words stressed on the antepenultimate syllable (*e.g.*, -olo in TAvoLo “table”) were defined as penultimate-stress primes. To examine the efficacy of stress neighborhood consistency based on word-ending, we carried out a pre-test, by presenting to adult readers the nonwords in a random order

in a word naming paradigm. The pre-test showed that stress was assigned to the nonwords according to their ending: 72% of nonwords with penultimate-stress neighborhood received penultimate stress and 78% of nonwords with antepenultimate-stress neighborhood received antepenultimate stress. Penultimate- and antepenultimate-stress nonwords were matched on: Length in letters (mean: 6.2 [sd: 0.5] vs. 6.3 [sd: 0.6]); number of consonant clusters (mean 0.3 [sd: 0.4] vs. 0.4 [sd: 0.5]) and initial phonemes.

Fifty penultimate- and 50 antepenultimate-stress nonwords were selected as primes. Target words were divided into 3 sets (10 each). Ten targets were assigned to the penultimate prime list, 10 targets to the antepenultimate prime list, and 10 targets were paired with a set of two simple geometric figures, square and triangle, each repeated 5 times. The latter condition was included to preserve interest and attention to the reading task in children, and was kept similar in the experiment with adults to have a perfectly matched control experiment. Stimuli preceded by figure primes were considered fillers, and not analyzed. Each target was preceded by 5 primes, as in Colombo & Zevin (2009; *cf.* Zevin & Balota, 2000). All target words had antepenultimate stress and they were congruent with the antepenultimate prime list, whereas they were incongruent with the penultimate prime list. The three different target lists were presented between-participants.

**Apparatus & Procedure.** The monitor was in VGA color. A voice key connected to the PC's real-time clock collected response latencies. The experiment was run using E-Prime software (Psychology Software Tools, Pittsburgh, PA). Participants were tested individually. They were instructed to read aloud each stimulus as fast and as accurately as possible. Stimuli were presented on the computer screen. In each trial, a fixation point was presented for 300 ms, followed by the stimulus in black color. At the start of articulation the letter string turned in red when the voice key responded. Response time was measured from the onset of the stimulus to the onset of articulation. The stimulus remained on the screen until the experimenter coded each trial as correct or as an error (stress or phonemic error) by pressing one of the keys of the keyboard. Advancement of trials was made by the experimenter, as soon as response coding was done. When the letter string disappeared, the next trial started immediately. Participants were audio-recorded to allow a further verification of experimenter's evaluation. Each participant received the two priming lists in separate blocks in a counterbalanced order; half of the participants received the penultimate-stress prime list first, while the other half was presented the antepenultimate-stress prime list first. The experimental blocks were preceded by a practice session with stimuli not included in the experimental trial.

## Experiment 2 – Adults

**Participants.** Twenty-four participants (6 males, mean age: 22.6 sd: 1.3) took part in the experiment. They were all Italian native speakers and had normal or corrected-to-normal vision.

**Materials, Method, Apparatus & Procedure.** The same as in Experiment 1.

## Results

### Experiment 1 - Children

**Prime analysis.** Overall nonword primes were read consistently with their stress neighborhood and this was true for both second graders and fourth graders (Table 1). However, younger children assigned penultimate (dominant) stress significantly more often than older children, especially when reading nonwords with antepenultimate-stress neighborhood (younger children assigned penultimate stress to 56% of the nonwords whereas older children assigned penultimate stress to 52% of the nonwords) and the difference was significant ( $\chi^2 = 4.16$ ,  $p < .05$ ).

Table 1: Children. Percentages of nonwords read with each stress pattern for each class.

	II grade		IV grade	
	Penult. stress	Antepen. stress	Penult. stress	Antepen. stress
Penultimate stress neighborhood	74%	26%	79%	21%
Antepenultimate stress neighborhood	37%	63%	23%	77%

#### Target analysis.

Responses shorter than 250 ms or longer than 3500 ms (5.8% of all data points) were excluded from the analyses. Naming times and errors were both analyzed using mixed-effects models, with class (II grade vs. IV grade) and stress congruency (primes and target sharing the same stress vs. primes and target with different stress) as fixed factors. Participants and items were treated as random factors. The models were fitted using the *lmer* function (*languageR* package, Baayen, Davidson, & Bates, 2008) in R software (version 2.11). Results for errors are reported in Table 2.

**Naming times.** The mixed-effects model was run with naming latencies as dependent variable and class and stress congruency as predictors. The model showed a main effect of class ( $\beta = -0.33$ , st. err. = 0.11,  $t = -2.89$ ,  $p < .01$ ), with fourth graders faster than second graders. No other effect reached significance (stress congruency:  $t = 1.5$ ,  $p > .1$ ; class by stress congruency interaction:  $t < 1$ ,  $p > .5$ ).

**Errors.** Two analyses were run, one considering stress errors and the other one considering phonemic errors. Both analyses were performed with accuracy as dependent

variable and class and stress congruency as predictors. When considering stress errors, the mixed-effects model showed a significant interaction between class and stress congruency ( $\beta = 1.36$ , st. err. = 0.4,  $z = 3.39$ ,  $p < .01$ ), with the effect of stress congruency being significant only for fourth graders. No other effect reached significance (both  $z$ ,  $< 1$ ). Differently, when considering phonemic errors, only the effect of stress congruency approached significance ( $\beta = 0.57$ , st. err. = 0.3,  $z = 1.89$ ,  $p < .1$ ), with more errors in the incongruent stress condition. No other effect reached significance (class:  $z = 1.3$ ,  $p > .1$ ; class x prime interaction:  $z = -1.4$ ,  $p > .1$ ). Inspection of means shows that the congruency effect was mainly due to second-graders (Table 2).

Table 2: Children. Mean error percentages for the targets in the two stress-prime conditions.

	Stress errors		Phonemic errors	
	II grade	IV grade	II grade	IV grade
Congruent stress prime	28%	13%	16%	17%
Incongruent stress prime	29%	31%	25%	18%

### Experiment 2 – Adults

**Prime analysis.** Participants read nonword primes according to their stress neighborhood, with no tendency to overuse the penultimate stress (penultimate and antepenultimate stress were assigned 53% and 47% of the times, respectively).

#### Target analysis.

Responses shorter than 250 ms or longer than 1500 ms (4.1% of all data points) were excluded from the analyses. Naming times and errors were both analyzed using mixed-effects models, with stress congruency (primes and target sharing the same stress vs. primes and target with different stress) as fixed factor. Participants and items were treated as random factors.

**Naming times.** The mixed-effects model was run with naming latencies as dependent variable and stress congruency as predictor. The effect was not significant ( $t = -1.1$ ,  $p > .1$ ).

**Errors.** Stress errors were few, consequently they were analyzed together with phonemic errors. A mixed-effects model was performed with response accuracy as dependent variable and stress congruency as predictor. The effect of stress congruency (congruent stress prime = 4% errors; incongruent stress prime = 10% errors), was significant ( $\beta = 1.38$ , st. err. = 0.50,  $z = 2.76$ ,  $p < .01$ ): Readers were more accurate when primes and target shared the same stress than when primes and target had a different stress.

## Discussion

In two reading experiments, we tested what kind of distributional information younger and older children use

for stress assignment, and whether stress priming affects both children and adults in reading Italian aloud. The results show two main findings: First, while both adults and older children assign stress to non-words (prime stimuli) according to their stress neighborhood, younger children do exploit stress neighborhood, but they also show a tendency to overgeneralize penultimate (dominant) stress in assigning stress. Second, participants were more accurate to read a target when it was preceded by a set of primes with the same stress (both primes and target received antepenultimate stress), than when it was preceded by a set of primes with a different stress (primes received penultimate stress and target antepenultimate stress). This pattern was found with older children and adult readers, but not with younger children. One might argue that reading is a very different task for younger and older children and that this fact might be sufficient to explain the data. Although we do not exclude any effect of task familiarity, we believe that a better explanation may refer to how the reading system develops and what lexical/sub-lexical strategies children adopt (*cf.* Peressotti, Mulatti, & Job, 2010).

In interpreting this pattern of results, we should consider the development of distributional knowledge first. Previous research has shown that stress neighborhood can be considered the main factor able to drive stress assignment in adult readers (Arciuli *et al.*, 2010; Burani & Arduino, 2004; Kelly *et al.*, 1998; Protopapas, Gerakaki, & Alexandri, 2006) and in connectionist simulations of Italian (Pagliuca & Monaghan, 2010). Some studies have suggested that also the bias toward the dominant stress pattern in the language might play a role in stress assignment, but only when readers heavily rely on a sub-lexical procedure (Colombo & Zevin, 2009; but see also Protopapas *et al.*, 2006, for a different perspective in languages other than Italian). Similar to what was found by Arciuli *et al.* (2010) with English-speaking children, our study suggests that readers may use two types of information for stress assignment, but their relative employment changes during the acquisition of reading. Differently from older children and adults, who assign stress on the basis of stress neighborhood alone, Italian young children assign stress to nonwords not only on the basis of stress neighborhood, but also of the distributional bias toward the dominant (penultimate) stress in their native language. This might be due to at least two reasons: First, children are more prone to use sub-lexical reading (Ziegler & Goswami, 2005), thus increasing the chance to apply the distributional general bias. Second, in developing their lexicon and the ability to analyze orthographic and phonological information, children might develop their distributional knowledge by discovering more subtle correspondences between word orthography and stress pattern. Thus, the development of distributional knowledge would follow a trajectory that goes from the more general bias toward the dominant stress to the more specific stress neighborhood, which may require time to develop.

Let us now consider the stress priming effect. Our results are in line with previous research that found stress priming effects in reading (Colombo & Zevin, 2009; Sulpizio *et al.*, in press b). The fact that the stress pattern of a word can be primed confirms the idea suggested in word production models that, when reading a word aloud, participants compute suprasegmental information independently of segmental information (Levelt *et al.*, 1999) instead of retrieving the word's prosodic information from the lexicon. Accordingly, we can assume that these two types of information are first computed separately by means of specific mechanisms, and then assembled together prior to word articulation. However, while both older children and adults show stress priming effects, younger children do not. This difference could be explained by assuming that, although the prosodic system of younger readers is fully developed (Juszyk, Houston, & Newsome, 1999), it is not yet able to exploit prosodic information from the context, namely, from the primes' stress pattern. A similar interpretation is supported by the pattern of phonemic errors made by young readers, which decrease in the congruent prime condition: This pattern suggests that the prime affects the target's computation, but only at the segmental level; differently, younger readers are not able to use stress information driven by the primes, as no effect of the primes' congruency emerged at the level of stress errors.

The CDP++ model of reading aloud (for English words; Perry, Ziegler, & Zorzi, 2010) can account for our data fairly easily. The model assumes that stress information can be both lexically retrieved and sub-lexically computed. At the sub-lexical level a connectionist network maps graphemes onto phonemes and the orthographic input onto a stress pattern. Moreover, the model assumes that the phonological output buffer includes two different components, namely the *stress output nodes* and the *phonemic output nodes*: The former are responsible for stress assignment and the latter for phoneme activation. During training the network may learn to associate specific orthographic cues with a specific stress (*e.g.*, the final sequence *-ola* with antepenultimate stress). Thus, the probability that a pseudoword will receive a certain stress depends on the strength of the connections established between the orthographic cues and stress position: The more frequent the association between an orthographic cue and a stress pattern, the stronger the connection between stress and orthography.

The assignment of stress according to stress neighborhood may emerge at the sub-lexical level, with the word final sequence driving stress assignment. This mechanism might work less efficiently in young children who are learning to read, because they have to learn which orthographic sequences may work as a strong cue for stress. Thus, young children might assign stress to nonwords on the basis of a more general distributional tendency such as the bias toward the dominant stress pattern in the language. The stress priming effect may occur at the level of the *stress output nodes*: When planning the target's articulation, readers

might be affected by the repeated pre-activation of the primes' metrical structure, which can be congruent or incongruent with the target. Thus, stress may be primed at the level of the phonological output buffer, when readers assemble the phonological unit that has to be articulated. Finally, the absence of a stress priming effect in younger children might be due to the absence of a fully developed stress system in the first stages of reading.

To conclude, the present study has shown two important aspects of the developmental trajectory of stress assignment in reading. First, when reading a stimulus aloud, readers make use of their distributional knowledge to assign stress and they do it since the first stages of reading development. However, the type of distributional knowledge exploited by readers changes developmentally: While younger readers are more prone to use general knowledge about the dominant stress pattern in the language, older readers are more affected by more specific distributional knowledge, namely stress neighborhood. Second, and more important, stress information can be computed separately from phonemic information, but young children are more likely to use information that has been extensively acquired - (*i.e.*, the dominant pattern in the language), rather than information gathered from the context (*i.e.*, the priming list). Taken together, the present findings suggest a final conclusion: At the early stages of reading, the word stress assignment subsystem appears partially underdeveloped.

### Acknowledgments

The study was carried out with the support of grant PRIN 2009 from the Italian Ministry of Education and Research, and grant "Progetti di Ateneo Bando 2007" to L. Colombo. We thank Josephine Trippi for running the experiments.

## Abstract

We introduce the “Doppel teleoperation system”, which isolates several physical traits from a speaker, to investigate how personal information is conveyed to other people during conversation. With the Doppel system, one can choose for each of the communication channels to be transferred whether in its original form or in the one generated by the system. For example, the voice and body motion can be replaced by the Doppel system while the speech content is preserved. This will allow us to analyze individual effects of physical traits of the speaker and content in the speaker’s speech on identification of personality. This selectivity of personal traits provides us with useful approach to investigate which information conveys our personality through conversation. To show a potential of this proposed system, we conduct an experiment to test how much the content of conversation conveys the personality of speakers to interlocutors, without any physical traits of the speakers. Preliminary results show that although interlocutors have difficulty identifying their speakers only by using conversational contents, they can recognize their acquaintances when their acquaintances are the speakers. We point out some potential physical traits to convey our personality.

## Introduction

Where does personality come from? Do we characterize other people from what they are saying or from how they behave? These issues about personality have been long studied in cognitive psychology. Recent progress has provided us with dimensions of personality to measure human personality (McCrae, Zonderman, Costa, Bond, & Paunonen, 1996) and cognitive models (Brunswik, 1956). Thanks to the establishment of such methodologies, personality studies have been gaining attention not only in cognitive science but also from the viewpoint of design of human-computer/-robot interaction (Fong, Nourbakhsh, & Dautenhahn, 2003; Nass, Moon, Fogg, & Reeves, 1995).

Many studies on personality have been devoted to clarifying what information conveys personality traits of an individual. They have revealed that there exists a strong relationship between physical traits and personality. For example, some studies reported, using criterion measures based on self and peer reports, that a person’s appearance, including facial expression (Berry, 1990, 1991; Little & Perrett, 2006) and clothing style (Naumann, 2009), enables other persons to judge the person’s personality accurately. While these studies were based on photographs of the face or full-body, other studies have shown that body movement (Kenny, Horner,

Kashy, & Chu, 1992) and voice (Scherer & Scherer, 1981; Borkenau & Liebler, 1992) also provide useful information for judging personality traits, especially extraversion.

Although these studies showed several communication channels in which personal traits are presented, the experimental setting was limited to the case where a judge observes a person: there was no conversation between them, although the contents of a conversation would likely be the most informative. A crucial difficulty in examining the relationship between physical traits and personality during a conversation is to isolate physical traits of an individual person from the conversation and to control their effects. Such isolation and control would allow us to investigate not only independent effects of physical traits and personal thought but also mutual interaction among them on identification of personality.

Interactive artificial agents might help us overcome this difficulty since they have been utilized as controllable “humans” to understand the cognitive mechanism of human adults or infants (Itakura, 2008; Yoshikawa, Shinozawa, & Ishiguro, 2007). In this context, some studies have addressed the problems of the behavior and appearance of the agents as contribution to both cognitive science and robotics, using a robot that has a very human-like appearance, called an android (Ishiguro, 2007). While typical androids are controlled as stand-alone agents, a teleoperated android, called a “geminoid”, which has a very similar appearance to a living individual (Sakamoto, Kanda, Ono, Ishiguro, & Hagita, 2007; Nishio, Ishiguro, & Hagita, 2007) has been developed as a telecommunication medium to address several issues on telepresence and self-representation (Straub, Nishio, & Ishiguro, 2010). This system enables an operator to have nonverbal and physical interaction, including body touch, gesture and facial expression, as well as verbal one with other people, by operating an android that might have a different appearance from the operator, remotely.

Although the geminoid system provides us with a way to isolate physical appearance from personality traits, it still transfers not only conversational content but also many other physical traits of its operator such as body movement, facial expression, and speech features. We solve this problem by assuming a speaker who gives content and an operator who acts as a “mediator”, which might distort speech features of the speaker as well as control the geminoid’s movement. The assumption of the mediator enables us to eliminate physical

Figure 1: Overview of Doppel teleoperation system. Arrows with yellow show communication channels to be conveyed to the operator or the interlocutor and their sources.

traits of the speaker in speech features such as voice sound and accent from the conversation: interlocutors receive the content from speakers and the others from the mediator and the geminoid. As a result, personal information in conversation is separated into physical traits (appearance, body movement, and speech features) and content of speech (personal thought). Such a system to isolate physical traits will allow us to convey some of personal information of the speakers and to replace the others with ones belonging to a geminoid and its operator selectively.

In this paper, we propose a teleoperation system called “Doppel”, which isolates several physical traits from conversation. This system allows us to analyze individual effects of physical traits of a speaker and content in the speaker’s speech on identification of personality by controlling the physical traits to be conveyed to an interlocutor. To show a potential of the system for investigating how personalities of speakers are conveyed to interlocutors, we report an experiment where identification of the speakers during conversation are tested.

In the rest of the paper, we first describe the proposed system. Next, we report an experiment that we conducted to verify how much content of conversation provides personalities of speakers for their interlocutors. Preliminary results show that although interlocutors have difficulty identifying speakers only using conversational content, they can recognize that they are talking with strangers or their acquaintance. Finally, we discuss what information might provide personalities of speakers for their interlocutors during conversation.

## Doppel Teleoperation System

Figure 1 shows an overview of the proposed system, called the “Doppel Teleoperation System”. The system is based on the telecommunication system for a teleoperated android and uses a “geminoid” that resembles a living individual (Sakamoto et al., 2007; Nishio et al., 2007). The existing system is used for an operator to communicate with remote people. Unlike a video conference system where we only

Figure 2: Geminoids. (a) Geminoid HI-1 (right) and the model (left). (b) Geminoid F (left) and the model (right).

provide visual and voice information, it is expected to convey the presence of the operator. We extend this system to isolate individual communication channels by separating the teleoperation system into two subsystems: one for a speaker to have a conversation with an interlocutor and the other for an operator to control voice and motion of the geminoid. In the proposed system, the speaker communicates with the interlocutor through the geminoid, hearing what the interlocutor says and talking into a microphone in another room. The operator hears what the speaker says and then repeats the speaker’s words in her/his way of speaking in another teleoperation room. Therefore, the system allows us to eliminate physical traits of a speaker during conversation: appearance from a geminoid, vocal information and motion one from the operator, and the content of conversation from the speaker. In the following section, we provide more detailed information about the system.

## Appearance:Geminoid

Appearance of a speaker is replaced with the interface between the speaker and an interlocutor. The interface should have human-like appearance to investigate the influence of physical traits on personality identification in human-human interaction. This is achieved by using a geminoid (Figure 2), which resembles an existing individual. Geminoid HI-1 is designed so that its appearance resembles a living male (Figure 2(a)). It has 50 degrees of freedom (DoFs) including 13 DoFs for facial expression. Geminoid F has a similar appearance to a living female (Figure 2(b)). Most of 12 DoFs are used for facial expression.

Both geminoids have two different controllers: a conscious behavior controller and an unconscious one (Sakamoto et al., 2007). While the conscious behavior controller is driven by command from an operator to change behavior of a geminoid based on a set of preprogrammed body motions, subtle expressed motions such as breathing, blinking, and trembling are added by the unconscious behavior controller to maintain the naturalness of the geminoid’s behavior. In addition to such semi-automatic control, lip movements of the geminoid are synchronized with those of its operator. This is realized by a facial feature tracking software through the camera in front of the operator.

### Content of conversation: Speaker

A speaker decides what a geminoid says, monitoring the conversation between the geminoid and an interlocutor. The words of the speaker to the interlocutor is conveyed not to the interlocutor but to the operator, who hears it in an operation room, through a microphone.

### Voice and motion: Operator

The operator controls a geminoid to convey verbal and non-verbal information about a speaker and the operator him/herself to an interlocutor. The operator repeats what the speaker says in the operator's way of speaking in front of a microphone, which is connected to the sound system located behind the geminoid. One might argue for using a system for speech information processing instead of a human operator. Due to the limitations of current technology for speech recognition, we decided to use a human operator.

In addition to conveying the words of the speaker, the operator controls how much s/he provides the interlocutor with physical traits of the speaker such as speed of speaking and accent, and movement. For example, if the operator repeats the speaker's words, mimicking the speaker's way of speaking, speech features of the speaker will help the interlocutor identify the speaker. As a result, the geminoid's voice and movement are presented to an interlocutor as a mixture of verbal information and non-verbal one from a speaker and an operator.

### Experiment: personal identification based on conversational content

The proposed system allows us to isolate communication channels from a speaker and design a new experimental setting that is difficult for existing methodologies. As a first step to verifying how we identify personality traits of other persons during conversation, we investigated whether people can identify a person using only conversational content and how much physical traits affect the identification of the person.

In the following experiments, we used geminoid F. To avoid the speaker being identified due to not conversational content but personal information, an operator was asked to replace the speaker's dialect and specific words to identify the speaker (e.g., the speaker's nickname) with standard dialect and general words (e.g., you), respectively though the content of what a speaker said was preserved.

Since it is difficult for ordinary people to make such replacement, we assigned a female actor as the operator. The lip and head movements of the geminoid F were synchronized with ones of the operator, while other body movements and facial expressions were ignored except for eye blinking, which was realized by the unconscious controller. The communication channels and their sources are summarized in Table 1.

### Working hypothesis and prediction

Although physical appearance, motion, and voice include personality traits, content of conversation should also provide

Table 1: Sources of communication channels during conversation in the experiments

Channel	Source
Appearance	Geminoid F
lip motion	Operator
Voice sound	Operator
Speaking speed	Operator
Accent	Operator
Conversational content	Speaker

much information to identify personality traits because it includes person's thoughts, opinions, and feelings. It will convey more personal information if speakers are acquaintances. Therefore, we verify whether the following hypotheses are established or not.

Hypothesis 1 (H1): people can identify a speaker by using only content of conversation.

Hypothesis 2 (H2): people can correctly identify more speaker by using only content of conversation in case where the speaker is an acquaintance than in case where the speaker is a stranger.

We conducted experiments with two different conditions to verify these hypotheses: *stranger* condition where a speaker and an interlocutor do not know each other and *acquaintance* condition where a speaker and an interlocutor know each other well. We will verify the H1 by evaluating accuracy of a guess of a speaker from among four possible candidates. H2 will be tested through comparison between the accuracy of the guess in the *stranger* condition and one in the *acquaintance* condition.

### Participants

Since the geminoid F has a female physical appearance, only female participants were recruited to eliminate the possibility that gender difference makes it easier for an interlocutor to guess actual speaker. Seventy-six Japanese females participated in the experiment. We made nineteen pairs of two persons who do not know each other for the *stranger* condition while there were nineteen pairs of close friends for the *acquaintance* condition. We assigned one of each pair as a speaker and the other as an interlocutor. The average age of all participants was 25.3 (SD = 6.7).

### Procedure

A subject as an interlocutor was asked to chat about a given topic with a speaker and to guess the speaker from among four possible speakers: the parted subject as a speaker ( $S_s$ ), the model of the geminoid F ( $S_g$ ), the operator of the geminoid F ( $S_o$ ), and the assistant of an experimenter ( $S_a$ ). The last three persons were fixed through all experiments and we confirmed that the interlocutor did not know them. The model and operator of the geminoid F have never been selected as

actual speaker in the experiment. Therefore, the selection of  $S_g$  or  $S_o$  by the interlocutor is assumed to be caused not by conversational content but by other physical traits of the geminoid F and the operator. It is implied that, while her/his guess was based on the appearance of geminoid F if the interlocutor selected  $S_g$ , s/he guessed from the movement and voice of the operator if the interlocutor selected  $S_o$ .

Each experiment consisted of six three-minute sessions. An experimenter selected a topic to be discussed and actual speaker from between  $S_s$  and  $S_a$  before each session. The topic was chosen from two different kinds of topics: common topics and delicate ones. The common topics were the topics which people have more chance to talk about (e.g., “how do you want to enjoy your life after your retirement?”). Some topics were related to personal histories such as Christmas gift that speakers got as a child or personal preference such as favorite type of man. The delicate topics were about what people have less chance to discuss (e.g., “should we revoke elder persons’ driving licences to obviate car accidents?”). The selected speaker was told to discuss the given topic through the geminoid with the interlocutor while the person who was not selected was told to listen to music with headphones so as not to hear the conversation between the actual speaker and the interlocutor. Three consecutive selections of the same speaker were avoided not to make the interlocutor recognize the speaker because of long conversation.

Before each experiment starts, each possible speaker was asked to talk about two different topics provided by an experimenter. The talk was videotaped for two minutes per topic. An interlocutor watched the videos of all talks to discern personalities of all speakers. After that, she was asked to rate their personalities with the Japanese Property-Based Adjective Measurement questionnaire (Hayashi, 1978), which has high correlation between its three components and the extraversion, openness and agreeableness components of the Big Five Model (McCrae et al., 1996).

After rating the personalities of all speakers, the interlocutor was led to the experimental room where the geminoid F was located. The operator and speakers ( $S_s$  and  $S_a$ ) were separated into different rooms, respectively. After a brief explanation about the specifications of geminoid F, the number of sessions and the duration of each session, the experimenter informed the interlocutor that actual speaker could change for each session. It was also noted that the geminoid was controlled by the operator whom the interlocutor saw in the video and she would talk based on her own thought or what one of the other speakers was saying. During a session, the actual speaker and the interlocutor asked each other questions about a given topic and responded to each other. After each session concluded, the interlocutor was asked to guess who the speaker was and to provide the reason for her guess. She also rated personality of the speaker with the questionnaire (Hayashi, 1978). After the experiment finished, the interlocutor was debriefed about the experiment.

Table 2: Average of accuracy rate of guessing in *stranger* condition and *acquaintance* condition

condition	accuracy rate
<i>stranger</i>	0.28
<i>acquaintance</i>	0.31
total average	0.29

Figure 3: Rate of guesses on each actual speaker in acquaintance condition.

## Evaluation

The performance of an interlocutor was evaluated with how often an interlocutor guessed right on actual speaker. Due to limited space, the analysis of personalities rated by interlocutors with the Japanese Property-Based Adjective Measurement questionnaire is not reported here.

## Result

Table 2 shows average accuracy rates of guessing actual speaker for two conditions and total average across subjects. Although the total average rate is slightly higher than the rate expected by chance (0.25), no significant difference was found between them ( $p = 0.13 > .05$  by binomial test). This result indicates that it is hard to guess who is talking from conventional content, rejecting our first hypothesis. We also tested the second hypothesis by comparing average accuracy rates between two conditions. However, there was no significant difference between them ( $p = 0.85 > .05$  by Wilcoxon test) although the rate in the *acquaintance* condition is slightly higher than one in the *stranger* condition. This result suggests that the difference between two conditions does not support the our second hypothesis.

In the *acquaintance* condition, an interlocutor talks with not only an acquaintance but also a stranger (i.e. the assistant). If she identifies their acquaintances more correctly than the stranger, the second hypothesis is supported within the *acquaintance* condition. Therefore, we compared performance of guessing the actual speaker when the acquaintance is the speaker with one when the stranger is the speaker in the *acquaintance* condition.

Figure 4: Accuracy rates of guessing on different actual speakers in the acquaintance condition.

Figure 3 shows the rate of guesses of speakers on each actual speaker in the acquaintance condition. The left bar in the figure shows the rate for acquaintances as actual speaker while the middle bar represents the one for the stranger ( $S_a$ ) as actual speaker. The bar on the right shows the rate in case where the guesses occurred by chance. The black part in each bar stands for the rate of guesses of acquaintances. As we can see, the guessing performance for acquaintances as actual speakers is slightly higher than the rate expected by chance. However, there was no significant difference between them ( $p = 0.17 > .05$  by binomial test). Interestingly, the guessing performance is significantly different when the stranger was the actual speaker ( $p = 0.00 < .001$  by binomial test). These results indicate that, while it is hard for the interlocutors to identify acquaintances as the actual speakers, they can recognize that the actual speakers are not their acquaintances.

The results shown in Figure 3 suggest that our second hypothesis is not supported. However, the low accuracy rate of the acquaintances might be caused by the strong conservative bias of the interlocutors when making judgment of actual speaker as their acquaintances. To distinguish accuracy from bias effects, we computed  $A'$  and  $B''$  scores (Grier, 1971) from hit rate (i.e., the rate of the guess of the acquaintance given acquaintances as actual speakers) and false-alarm rate (i.e., the rate of guess of acquaintance given the stranger as actual speaker). The scores showed that the interlocutors are sensitive to their acquaintance ( $A' = 0.80$ ) though they have strong conservative bias against guessing their acquaintances ( $B'' = 0.70$ ). Both scores were higher than ones in case of guessing the stranger ( $S_a$ ) as actual speaker ( $A' = 0.54, B'' = 0.036$ ). In fact, it was revealed that the interlocutors identify their acquaintances significantly when we calculate the accuracy rate given that the interlocutors answered that speakers were their acquaintances. Figure 4 shows the accuracy rates of guessing the actual speakers in *acquaintance* condition. As can be seen, the guessing performance for their acquaintances as actual speaker is much higher than the performance expected by chance. Actually, there was significant difference between them ( $p = 0.00 < 0.001$  by binomial test). We cannot find such difference for the guessing performance for the assistant as actual speaker (see the middle bar in Figure 4). These re-

Table 3: Selection probability of possible speakers

speakers	selection probability
the model of geminoid F	0.285
the operator	0.241
the assistant	0.263
the subject as a speaker	0.206

sults imply that the interlocutors identify their acquaintances as the actual speaker, supporting the second hypothesis.

We also calculated probabilities of guessing each possible speaker as the actual speaker to test how much physical traits can affect the identification of speakers (Table 3). Although the probabilities of selecting the geminoid model or the operator are slightly higher than that of selecting subjects as speakers, we were able to see no significant difference among them. This might imply that no physical trait is much stronger than others when several traits are presented.

## Discussion

The results revealed that it is difficult for people to identify a person without her/his physical traits: physical appearance, body movement, and speech features. In fact, after the experiments, some interlocutors reported that they felt as if the geminoid had another new personality, not one of possible speakers. Even though some results did not support our hypotheses, the results gave us fruitful insights. Especially, it is interesting why it was easy for the interlocutors to recognize that actual speaker is not their acquaintances. Exclusion of some physical traits presented in the experiment will reveal what information provides interlocutors with enough information to make the judgment.

The accuracy and response bias scores suggested that the low accuracy rate of guessing acquaintances might be caused by the conservative bias of the interlocutor for the guess. This finding was supported by the high accuracy rate of guessing when the interlocutors guessed their acquaintances as the actual speaker as shown in Figure 4. Since our second hypothesis was partially supported not between conditions but in the acquaintance condition, further verification is needed.

The accuracy rates shown in Table 3 tell us that there is no significant effect of physical traits on personal identification. This might implies that the identification of personality during conversation results from mutual interaction among physical traits and conversational content. The investigation of such interaction seems difficult for existing approaches because they needs to extract single modality from all modalities and exclude the others. Our system is useful for such investigation because it allows us to examine not only single effect of the physical traits and conversational content but also the mutual interaction among them by controlling the presented information selectively. We will conduct experiments with different combinations of physical traits to investigate how physical traits and conversational content interact

with other traits as a future work.

One concern in this system is the influence of the geminoid on interlocutors' judgment. Previous studies have reported that people respond to an android as they respond to a human if it shows human-like behavior (Shimada & Ishiguro, 2008). Since we designed the geminoid so as to resemble human in appearance and movement, it is expected that the subjects consider the geminoid as a "human". However, it is well-known as uncanny valley (Mori, 1970) that even small lacks of human likeness affect human perception of androids. Therefore, how human likeness of androids affect human judgmental process should be addressed in the future.

We should point out that the interlocutors still extracted some physical traits of their speakers through conversation even though we tried to eliminate this possibility in the conversation. More precisely, they used some speech features to guess actual speakers: timing of speech, duration of speech, and expression of feedback to the interlocutors' comments like "Really?", "Exactly", and "No way!". In addition, it turns out that interlocutors might use speed of speech and accent to guess actual speakers in preparatory experiments. A detailed investigation of physical traits including such speech features is also valuable as future work.

## Conclusion

We introduced the "Doppel teleoperation system", which isolates several physical traits from conversation, to investigate how personal information is conveyed to other people during conversation. With the Doppel system, one can choose for each of the communication modalities to be transferred whether in its original form or the one generated by the system. This will allow us to analyze individual effects of physical traits of the speaker and content in the speaker's speech on identification of personality. We tested how much content of conversation conveys the personality of speakers for interlocutors, without any physical traits of the speakers. Preliminary results showed that although interlocutors have difficulty identifying their speakers only by using conversational content, they could recognize that they were talking with their acquaintances. We hope that this system helps us understand our cognitive mechanism of our personality.

## Abstract

In this paper, we investigated the process of interestingness cognition in metaphor comprehension. We did this from the point of view that the interestingness of a metaphor (e.g., “*life is like a gamble*”) is related to its interpretative diversity. Two studies were conducted to assess this phenomenon: Study 1 (interpretation-production) and Study 2 (interpretation-presentation study). In Study 1, we observed that a greater number of interpretations were produced from a metaphor that was interesting and easy to understand as compared to one that was less interesting and difficult to understand. In Study 2, we observed that a metaphor was more interesting when more information on simile interpretation was presented. On the basis of these results, we discuss the relationship between the process of metaphor comprehension and metaphor evaluation.

**Keywords:** metaphor/simile comprehension; interpretive diversity; interestingness.

## Introduction

Sentences such as “*life is like a gamble*” and “*marriage is like a refrigerator*” include comparative senses. Such sentences, consisting of a paired topic and vehicle, which we refer to as a “metaphor” (strictly a “simile”), indicates similar points between two words: *life* is like *a gamble* (both unpredictable and implying risk) and *marriage* cools a relationship or keeps it fresh, as does a *refrigerator* for its contents. Similarity is very important for metaphor comprehension. Recent studies have discussed similarity cognition or the factors that affect similarity cognition in metaphor comprehension. In fact, most studies discuss the relationships between similarity cognition and the process of metaphor comprehension (e.g., Gentner, 1983; Ortony, 1979; Tversky, 1977).

## The Process of Metaphor Comprehension

Similarity cognition in metaphor comprehension is described simply as “the similarity between the topic and vehicle.” The question of similarity involves two forms of nuance: the qualitative sense and the quantitative sense. As illustrated in aptness views (e.g., Chiappe & Kennedy, 1999; Chiappe, Kennedy, & Smykowski, 2003; Jones &

Estes, 2006), the former refers to the degree (“goodness” and “adequacy”) to which the topic and vehicle are similar. As defined in Chiappe and Kennedy (2001), goodness and adequacy indicate the extent to which a comparison captures the important features of the topic. For example, *gamble* includes features salient in, and applicable to, the nature of *life*: in gambling’s sense of “unpredictability,” *gamble* adequately represents an important aspect of *life*. Likewise, both *a refrigerator* and *marriage* cool something, but *marriage* is comparatively difficult to express with a *refrigerator*. Previous studies have shown that this type of similarity affects the process of metaphor comprehension. Jones and Estes (2006) experimentally revealed that the strength of metaphor aptness predicts metaphor/simile preference, reading time for a metaphor, and the ease of interpretation of a metaphor. An apt relationship between the topic and vehicle creates a preferential metaphorical (categorical) expression, is read faster, and is rated as easier to understand than a less apt relationship.

According to the quantitative view, similarity cognition is based on the number of features shared by both the topic and the vehicle. If this number is large, similarity cognition between the topic and vehicle is strong. In the process of metaphor comprehension, these shared features are generated as metaphor interpretation: the metaphor with the most shared features is predicted to produce the most interpretations. In previous studies, simulation results have shown reliable evidence that the productivity of metaphor interpretation, such as interpretative diversity (Utsumi & Kuwabara, 2006; Utsumi, 2007), is more closely related to the process of metaphor comprehension than to the goodness of similarity (i.e., metaphor aptness). Thus, the topic-vehicle relationship that produces several interpretations is the preferred metaphor or simile.

## The Process of Metaphor Evaluation

As described above, the similarity cognition of a metaphor plays an important role in the process of metaphor comprehension. On the other hand, some previous studies have suggested that similarity cognition is also related to the process of metaphor evaluation, such as the rhetoric effect and how funny and interesting a metaphor is.

A metaphor is understood through its cognitive effect, which is not only the enhancement of word meaning (Blasko & Connine, 1993; Gernsbacher, Keyser, Robertson, & Werner, 2001; Taira & Kusumi, 2011) but also its pragmatic effect (Sperber & Wilson, 1994). The former has been revealed to be affected by the strength of the similarity cognition, such as aptness (Blasko & Connine, 1993; Taira & Kusumi, 2011); the latter appears to be related to similarity cognition. For example, Roberts and Kreuz (1994) show that all figurative expressions have some discourse goal. Among them, a metaphor (e.g., “*life is a gamble*”) and a simile (e.g., “*life is like a gamble*”) have different pragmatic goals. One difference is that the simile is used as a humorous expression, while the metaphor is not. Previous studies have shown that the simile is a comparative expression based on similarity cognition, unlike the metaphor (Bowdle & Gentner, 2005; Jones & Estes, 2006) so that similarity cognition is related to humor.

In consideration of the above, we examined the relationship between the simile comprehension process and its evaluation process in a previous study (Taira, Nakamoto, & Kusumi, 2006). The aim of that study was to examine the process of interestingness cognition through correlations between factors affecting the process of simile comprehension. We studied 75 undergraduate native Japanese speakers and employed 30 Japanese similes (e.g., “*life is like a gamble*,” “*marriage is like a refrigerator*”). Through a simple rating task, the ease of comprehension, similarity, familiarity, unpredictability, and interestingness of each simile were measured. In addition to these ratings, the number of interpretations for each simile was collected in another study where participants were required to write out their interpretations of the simile.

Table 1: Correlations between the factors of metaphor comprehension in Taira, Nakamoto, and Kusumi (2006)

Factors	2	3	4	5	6
1. Ease of Comprehension	.960	.947	.938	.740	.347
2. Similarity	-	.933	.927	.705	.382
3. Familiarity	-	-	.967	.696	.302
4. Unpredictability	-	-	-	.712	.300
5. Interestingness	-	-	-	-	.533
6. Number of Interpretations	-	-	-	-	-

$N = 30$

Correlations between the metaphor factors are shown in Table 1, and the results of a path analysis based on the correlation data are shown in Figure 1. The results indicate that both similarity and familiarity, considered factors related to similarity cognition (Chiappe & Kennedy, 2001), are related directly to ease of comprehension. Furthermore, the ease of comprehension and the number of interpretations directly affect simile interestingness: the more easily the simile is understood and the more interpretations the simile produces, the simile is interpreted as more interesting.

Figure 1: The process of interestingness cognition (Taira, Nakamoto, & Kusumi, 2006)

## The aim of our research

Our previous studies suggest that the similarity cognition of a metaphor, especially quantitative similarity, is related not only to the process of metaphor comprehension but also to the process of metaphor evaluation (i.e., interestingness cognition). However, such results are only suggested by correlational data; it is unknown whether a metaphor that is interesting and easy to understand really produces several interpretations and whether metaphor interpretation directly affects interestingness cognition. It is unclear whether the interestingness of a metaphor is based on the metaphor’s properties or an individual’s action. In this paper, we investigated the process of interestingness cognition in metaphor comprehension.

In Study 1, we examined the number of interpretations for a simile. Our previous study did not reveal the process of interpretation production in simile comprehension; thus, we did not determine whether an individual could produce several interpretations from a simile that is interesting and easy to understand. In Study 1, we examined the number of interpretations for various metaphors with different levels of interestingness and ease of comprehension.

In Study 2, we examined whether the interpretation itself increases the interestingness cognition. As in Study 1, interestingness cognition is inferred through correlational relationships. If this prediction is correct, a metaphor will be judged more interesting when more interpretations of the metaphor are presented. For Study 2, we provide experimental data on the relationship between the interpretation and the interestingness of metaphors.

## Study 1

The aim of Study 1 was to confirm that an individual produces more interpretations for a more comprehensive and interesting metaphor, and vice versa.

## Method

**Participants** 800 participants were recruited from an internet research company. All were native Japanese speakers.

**Materials** Thirty-six Japanese similes were selected from the materials used in Taira and Kusumi (2009); some were also selected from materials used in our previous study

(Taira, Nakamoto & Kusumi, 2006). For these similes, Taira and Kusumi (2009) examined interestingness and ease of comprehension using 5-point scales (1 = “not at all interesting or easy to understand” to 5 = “very interesting or easy to understand”). They were clustered within three simile types: 12 similes that were seen as highly interesting and very easy to understand (e.g., “*life is like a gamble*.” interestingness,  $M = 3.21$ , ease of comprehension,  $M = 4.04$ ), 12 similes seen as moderately interesting and easy to understand (e.g., “*a husband is like jewelry*.” interestingness,  $M = 2.81$ , ease of comprehension,  $M = 3.38$ ), and 12 similes seen as less interesting and difficult to understand (e.g., “*marriage is like a refrigerator*.” interestingness,  $M = 2.38$ , ease of comprehension,  $M = 2.36$ ). The correlation between interestingness and ease of comprehension was very strong ( $r(36) = .88$ ). This result is similar to results obtained in Taira, Nakamoto, and Kusumi (2006); thus, the material selection in Study 1 was appropriate. In this paper, we defined each type of simile within a high-, middle-, and low-rating group.

**Procedures** This study was part of an omnibus internet survey that measured higher-order literacy. The monitors participated in the survey on the internet. They were required to access the website described by the internet research institute and to answer questions relevant to our study. Three similes had been selected from each category. Participants were required to provide as many interpretations of each simile as possible. The interpretations were typed into a textbox on the webpage.

## Results and Discussion

Between 57 and 86 participants produced interpretations for each simile. Data were coded and clustered. Through this procedure, the number of interpretation units for each simile was examined. We defined an interpretation unit as the component included within the participant’s text with an independently important sense for the metaphor’s interpretation. For example, if one participant produces the interpretation “it is unpredictable and followed with any risk. It does not describe what will happen next” for “*life is like a gamble*,” two interpretation units are produced because the second sentence includes the same unit that appears in the first sentence.

Table 2: Mean number of interpretation units

	low-rating	middle-rating	high-rating
interpretation	1.25	1.37	1.51
unit (SD)	(.73)	(.73)	(.92)

$N=800$

There were strong correlations between the interpretation unit and ease of comprehension ( $r(800) = .498$ ) and interestingness ( $r(800) = .404$ ) in Taira and Kusumi (2009). These results suggest that participants produced more interpretations for similes that were more interesting and easy to understand. In addition, the mean of the interpretation unit per participant is shown in Table 2. The

mean data were analyzed through one-way ANOVAs with participants ( $F_p$ ) and items ( $F_i$ ).

The main effect of rating group was significant ( $F_p(2, 1598) = 36.86$ ,  $\eta^2 = .02$ ;  $F_i(2, 22) = 5.14$ ,  $\eta^2 = .24$ ;  $ps < .001$ ). Multiple comparisons revealed significant differences between the low and middle rating groups ( $t(1598) = 4.00$ ,  $r = .15$ ), low and high rating groups ( $t(1598) = 8.58$ ,  $r = .28$ ), and middle and high rating groups ( $t(1598) = 4.58$ ,  $r = .16$ ).

The results show that participants produced different numbers of interpretations according to their ease of comprehension and interestingness. This is somewhat consistent with results from Taira, Nakamoto, and Kusumi (2006). However, both ease of comprehension and interestingness in Study 1 were defined through data from our previous studies (Taira & Kusumi, 2009). Results from Study 1 did not indicate whether participants really conceived the metaphor as interesting and easy to understand. This problem was addressed in Study 2.

## Study 2

Study 1 revealed relationships between the ease of comprehension/interestingness of a metaphor and its number of interpretations. From these results, however, we cannot ascertain whether interestingness cognition is followed by metaphor interpretation or whether interestingness cognition follows metaphor interpretation. In Study 2, we controlled the number of metaphor interpretations and investigated the effect of interpretation on interestingness cognition.

## Method

**Participants** Fifty-four participants took part in Study 2. All were native Japanese speakers and had not participated in Study 1.

**Materials** From Study 1, the 12 similes that were defined within the high-rating group (e.g., “*life is like a gamble*”) and the 12 similes that were defined within the low-rating group (e.g., “*marriage is like a refrigerator*”) were selected. For each simile, three relevant simile features (e.g., for “*life is like a gamble*,” “*unpredictable*,” “*followed with any risk*,” and “*needing strategy*”) were applied. The three relevant features were selected from the first, second, and third most popular interpretation units produced in Study 1.

**Procedure** Study 2 was composed of three tasks: a rating task, a reading span task (RST), and a re-rating task. These tasks were performed in aforementioned order.

The rating task was a simple rating task in which participants were required to rate the ease of comprehension, interestingness, and unpredictability of the similes. Each factor was rated on 7-point scales (1 = “very difficult to understand,” “not at all interesting,” and “very predictable” to 7 = “very easy to understand,” “very interesting,” and “very unpredictable”).

For the RST, a standardized procedure of the Japanese RST (Osaka & Osaka, 1994) was performed. For this task, 2 to 5 sentences with one word underlined were presented in order; participants were required to read aloud each

sentence. After all the sentences were presented and read, participants were required to read all the underlined words without the sentence. The task included 22 trials: the first two were practice trials and the remaining 20, true trials. The RST was used only as a filler task between the rating and re-rating tasks.

Figure 2: Design of the re-rating task in Study 2

The re-rating task was composed of three phases (see Figure 2). During the first phase, three information units were presented to participants. The information unit was either the feature (e.g., “unpredictable,” “followed with any risk,” or “needing strategy”) relevant to the simile (e.g., “life is like a gamble”) or a simple addition-subtraction calculation formula (e.g., “2 + 4” or “1 - 5”). The composition of the information units included three features without a calculation formula, one feature and two calculation formulas, and no features and three calculation formulas. Participants were required to comprehend the information units because they would perform a recall task after this phase. During the second phase, participants were required to rate the ease of comprehension, interestingness, and unpredictability of the similes in the same manner as during the rating task. Participants were instructed to re-rate the similes based on their current impression (not based on their previous rating). During the third phase, participants were required to recall features and calculation formulas learned during the first phase. After participants finished the third phase, the next trial began. This task included 26 trials: the first two were practice trials.

## Results and Discussion

The scores for ease of comprehension, interestingness, and unpredictability in the rating and re-rating tasks were examined. Mean scores for ease of comprehension,

interestingness, and unpredictability for the high rating group are shown in Figure 3, and the scores for the low rating group are shown in Figure 4.

Figure 3: The mean scores (SD) of the high-rating group

**High-rating group’s results** For the high-rating group, the ease of comprehension score was very high, and a series of 2 (task type: rating/re-rating) x 3 (the number of feature: 0/1/3) repeated-measures ANOVAs revealed a significant main effect of task type ( $F(1, 53) = 4.53, p < .005, \eta^2 = .00$ ) but no main effect of the number of features ( $F(2, 106) = .47, \eta^2 = .00$ ) or any interactions ( $F(2, 106) = .87, \eta^2 = .00$ ). Likewise, ANOVAs were conducted on the interestingness and unpredictability scores. The unpredictability result revealed no significant main effects of task type ( $F(1, 53) = .06, \eta^2 = .00$ ), the number of features ( $F(2, 106) = .51, \eta^2 = .00$ ), or any interactions ( $F(2, 106) = .51, \eta^2 = .00$ ). The

result of interestingness also showed no significant main effects of task type ( $F(1, 53) = .50, \eta^2 = .00$ ) and the number of features ( $F(2, 106) = 2.96, p < .10, \eta^2 = .01$ ), and no significant interaction ( $F(2, 106) = 1.48, \eta^2 = .00$ ).

If the prediction that metaphor interpretation directly affects and increases interestingness cognition is correct, the results from the high rating group suggest that the simile of the high rating group originally produced several interpretations (from Study 1); thus, the scores for each rating task factor were the same as the scores in the re-rating task where interpretations were presented.

Figure 4: The mean scores (SD) of the low-rating group

**Low-rating group's results** For the low-rating group, a series of 2 (task type: rating/re-rating) x 3 (the number of features: 0/1/3) repeated-measures ANOVAs revealed significant main effects of task type ( $F(1, 53) = 56.89, p$

$< .001, \eta^2 = .08$ ) and the number of features ( $F(2, 106) = 9.46, p < .001, \eta^2 = .04$ ) in the ease of comprehension scores, as well as a significant interaction ( $F(2, 106) = 15.05, p < .001, \eta^2 = .02$ ). To deconstruct the interaction, Ryan's multiple comparisons test indicated simple main effects of task type on both the 1-feature and 3-feature conditions ( $F_s(1, 159) = 42.79, 63.04, p_s < .001, \eta^2 = .06, .08$ ). Simple main effects of the number of features on the re-rating task were also significant ( $F(2, 212) = 20.96, p < .001, \eta^2 = .07$ ): in the re-rating task, the scores in both the 1-feature and 3-feature conditions were higher than the 0-feature condition ( $t_s(106) = 2.59, 4.32, p_s < .05, .001, r = .28, .40$ ). On the other hand, scores for the 3-feature condition were not significantly higher than the 1-feature condition ( $t(106) = 2.08, r = .14$ ).

For the interestingness scores, there were also significant main effects of task type ( $F(1, 53) = 8.74, p < .005, \eta^2 = .01$ ) and interactions ( $F(2, 106) = 3.39, p < .05, \eta^2 = .01$ ) but no significant effects for the number of features ( $F(2, 106) = .50, \eta^2 = .00$ ). Ryan's multiple comparisons test also indicated simple main effects of task type in both the 1-feature and 3-feature conditions ( $F_s(1, 159) = 5.54, 10.62, p_s < .05, .005, \eta^2 = .01, .02$ ), but no simple main effect of the number of features for the re-rating task ( $F(2, 212) = 2.58, p < .10, \eta^2 = .01$ ). Conversely, for the unpredictability scores, there were no significant main effects (task type:  $F_s(1, 53) = .51, \eta^2 = .00$ ; number of features:  $F_s(2, 106) = 1.06, \eta^2 = .01$ ), or interactions ( $F_s(2, 106) = 1.80, \eta^2 = .00$ ).

These results suggest that the presentation of metaphor interpretation, which is related to similarity cognition, affects the process of metaphor comprehension: the interestingness of a metaphor might be increased through interpretations. This is consistent with the prediction that interpretative action significantly affects interestingness cognition. Our results also confirm previous studies suggesting that metaphor appreciation is based on the resolution of incongruity (Utsumi, 2002; Utsumi, 2005). However, the solution of unpredictability was not detected by results from Study 2. One possible interpretation is that unpredictability might be attributed not to the simile but to the interpretation itself. The low-rating similes are generally difficult to comprehend and produce its interpretations (from Study 1) so that the presented interpretations in Study 2 can be also unexpected to the participants. If some participants confounded this cognitive process with the task judgment that required the evaluation of the simile itself, results from the low-rating group are probable. This problem needs to be addressed in future research by using more strict instructions and experimental paradigms.

## General Discussion

The current studies have provided experimental evidence of metaphor comprehension/evaluation. Previous studies have only revealed relationships between these constructs and were unable to fully determine whether evaluation results are based on the metaphors' properties or individuals' inner processes.

Our results suggest that metaphor evaluation is based on interpretative action. Moreover, our results indicate that metaphor comprehension is strongly affected by whether the connection between two different concepts is discovered. Thus, our results support the quantitative view of metaphor comprehension (Utsumi, 2007). However, our results do not fully discount the qualitative view given that the number of interpretations observed depends on the context, the saliency of interpretation, and an individual's cognitive ability. Our task paradigm, especially that of Study 2, shows incongruence between the interpretation during the task and the interpretation that the individual produces. We usually produce metaphor interpretations when reading or listening to them and unaided by any relevant information. We typically are unable to refer to adequate interpretations, as were participants in Study 2. In future research, we will examine the relationship between metaphor interpretation and metaphor evaluation through a task requiring participants to produce interpretations of metaphors.

Previous studies have discussed the relationship between the process of comprehension and an individual's cognitive ability, such as working memory (e.g., Chiappe & Chiappe, 2007; Pierce & Chiappe, 2009; Pierce, McLaren, & Chiappe, 2010). However, there are few studies examining the relationship between evaluation processes, such as interestingness, and working memory. Future research will need to examine the working memory factor, which is predicted to affect the process of both comprehension and evaluation.

## Abstract

The purpose of this study was to examine psychological factors that affect the transmission of rumor and criticism in social media during disasters. 40 students at Chiba University evaluated 10 rumor tweets and corresponding 10 criticism tweets that were posted in Twitter after the Japan March 11 Earthquake. Among some psychological factors, only importance was related to intended transmission of rumor. Surprisingly, accuracy and anxiety were not predictors of any transmission. Estimated transmission of criticisms was higher when its importance was high, while that of rumor did not vary according to importance. Interestingly, although participants estimated that criticisms were spread more than rumor, they intended to transmit rumors as much as criticisms.

**Keywords:** Rumor; criticism; disaster; social media; technology; communication

## Introduction

A 9.0 magnitude earthquake hit northeastern Japan on March 11, 2011. The Great East Japan Earthquake triggered powerful tsunami waves and a series of aftershocks, which caused a devastating damage to the country.

During the disasters, social media played an important role in obtaining and transmitting information to understand the situation. An example is Twitter, which enables its users to send and read text messages of up to 140 characters, known as “tweets,” and to forward a message by re-tweeting a tweet to followers through a single click.

Communications during disasters increasingly relies on social media like Twitter. One reason is that social media allow immediate and interactive information transmission. This advantage, for example, led to the discovery and rescue of some individuals who were isolated in a disaster area after the Japan Earthquake. Although social media can play an important role in sharing information and coordinating disaster response, social media can also facilitate the dissemination of false information, potentially creating widespread panic. After the Japan Earthquake, for example,

Twitter was immediately filled with tweets about the disaster that included not only useful information but also false rumors (Ogiue, 2011; Tachiiri, 2011). The spread of false rumors about the disaster became a major social problem, and the Japanese government called attention to false rumors on the Internet.

Given the growing use of social media in people’s everyday life, cognitive science research needs to examine how people process information using social media technologies. This work contributes to this need by analyzing the transmission of rumor and criticism in Twitter after the Japan Earthquake. During disasters, factors such as time pressure and psychological stress come into play, and each individual’s decision and action can have significant impact. For instance, the immediate and far-reaching spread of false information can be detrimental. Thus, it is important to study how users interact with information in social media.

Although Twitter is a new technology started in 2006, the spread of false rumors during disasters is not a new phenomenon (e.g., Prasad, 1935; Sinha, 1952). For example, Prasad (1935) categorized rumors after the great Indian earthquake of 1934. He found that the same types of rumors about earthquakes appear again and again in different locations during the past 1,000 years (Prasad, 1950).

Rumor study caught attention after World War II (see Rosnow & Foster, 2005). Rumor was defined as “*unverified and instrumentally relevant information statements in circulation that arise in contexts of ambiguity, danger, or potential threat and that function to help people make sense and manage risk*” (DiFonzo & Bordia, 2007, p.13). It was distinguished from gossip, defined as an evaluative statement about someone’s private lives.

Past rumor studies revealed psychological factors that affect rumor behavior, such as accuracy, anxiety, and importance of rumors, and examined rumors in different situations, including universities, organizations, and communities (Anthony, 1973; DiFonzo & Bordia, 2000; Rosnow, 1991; Rosnow, et al., 1988; Walker & Beckele,

1987). However, few of the past work have examined rumors in social media, which allow users to communicate with a large number of people who are physically distant. Thus, it is unclear whether we can apply the findings from past studies to rumor transmission in Twitter.

In addition to the abundance of rumors in Twitter, we noticed that many people tried to stop the spread of false rumors by criticizing the rumor tweets. It was not only the government and organization but also many individual Twitter users who posted criticism tweets. A number of studies have shown that refutation decreases the level of belief in rumors (e.g., Allport & Postman, 1947; Bordia, et al., 2000; Iyer & Debevec, 1991). Thus, criticism tweets could minimize the impact of false rumors by making users critical. Even if false rumors spread widely in Twitter, the negative effect of false rumor would be curbed if criticisms also spread. For this reason, examining how criticisms spread in Twitter deserves attention.

In the current study, we examine the psychological factors that affect rumor and criticism transmission using actual tweets posted after the Japan Earthquake. Specifically, we study whether perceived accuracy and importance of tweets and anxiety arising from the tweets relate to the intended and estimated transmission of the tweets.

## Method

### Participants

Forty students (18 male, mean age 20 years) from Chiba University in Japan participated for course credit. In addition, they received a gift card in the amount of 500 Japanese yen (about \$6.5). The experiment was conducted from October 19 to November 1, 2011. Chiba University is located in one of the areas affected by the disasters.

### Stimuli

We collected 10 rumor tweets related to the disasters following the Japan Earthquake and 10 criticism tweets that criticized the corresponding rumor tweets (see Appendix). Each tweet was posted in Japanese on Twitter between March 11 and September 7, 2011. Each of the 20 tweets was converted to a 700×162 pixels image in the PNG format (see Figure 1). The user name associated with each tweet was generated by randomly combining alphabet and number. The image also contained the actual date when the original tweet was posted. We created each criticism tweet by adding the word “RT” (an abbreviation for Re-Tweet), the user name of the corresponding rumor tweet, and part of the rumor tweet to the criticism (see Figure 1, bottom). The maximum number of characters in each tweet image was 140 in Japanese.

### Design and Procedure

The within-subject factors were tweet type (rumor vs. criticism) and transmission (intended vs. estimated). Participants accessed the experiment through the Internet using computer. They were instructed to answer all

questions within 50 minutes. The experiment consisted of the four phases in the following order:

**1. Rumor tweet** Participants answered the following eight questions about each rumor tweet: (1) Familiarity – Have you heard this information? (Yes, No); (2) Anxiety – How anxious did you feel when you heard this information? (1 Not at all, 7 Highly anxious); (3) Importance – How important do you think this information is? (1 Not at all, 7 Highly important); (4) Intended receiver – Who should know this information? (Family, Friend, Victims, Many Japanese, Many people abroad, Anyone, Other); (5) Intended transmission – How many people do you think should know this information?; (6) Self-accuracy – How accurate do you think this information is? (1 Not at all, 7 Highly accurate); (7) Estimated transmission – How many people do you think have already known this information at present?; (8) Others-accuracy – How accurate would others think this information is? (1 Not at all, 7 Highly accurate). Each tweet was presented in a random order.

**2. Criticism tweet** The design and procedure were the same as those of the rumor tweet phase.

**3. Demographic information** There were demographic questions and other questions about the degree of damage experienced and familiarity with Twitter and media.

**4. Debriefing** Each participant was explained the purpose of the experiment. It was emphasized that the tweets in the experiment might be false, and that the spread of false rumor was becoming a social problem after the disaster. In addition, for further information, we recommended useful books and websites that examined the false rumors related to the disaster.

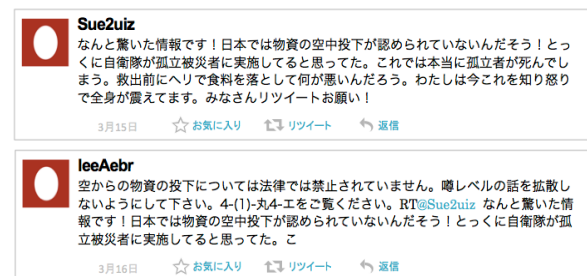

Figure 1: Top) A rumor tweet – “Air drop of supplies is not allowed in Japan! I though it has already been done by the Self-Defense Forces. Without it, the isolated people will die! I’m trembling with anger. Please retweet!” Bottom) A corresponding criticism tweet – “Air drop of supplies is not prohibited by the law. Please don’t spread rumor. Please see 4-(1)-丸 4-エ.”.

## Results and Discussion

On average, the tweets we used were relatively unfamiliar to the participants. The range of proportion of participants who were familiar with 10 rumors was from 0% to 38% ( $M = 22.5\%$ ). That of 10 criticisms was 0% to 43% ( $M = 9.8\%$ ). The overall results are shown in Appendix.

Table 1: Pearson's Coefficients of Correlation in Rumor and Criticism tweet

	Rumor tweet					Criticism tweet				
	1	2	3	4	5	1	2	3	4	5
1. Self-accuracy										
2. Others-accuracy	.62**					.79**				
3. Anxiety	.64**	.35*				.29	.14			
4. Importance	.80**	.44**	.71**			.73**	.59**	.57**		
5. Intended transmission	.29	.22	.02	.32*		.24	.28	.08	.26	
6. Estimated transmission	-.05	.14	-.23	-.11	.31*	.13	.16	.26	.03	.47**

Note. <sup>†</sup> $p < .10$ , \* $p < .05$ , \*\* $p < .01$

We removed outliers of intended and estimated transmissions using the Smirnov-Grubbs test. Analyses were repeated until no additional outliers were observed.

We examined the relationship between the four psychological factors (self-accuracy, others-accuracy, anxiety, and importance) and transmission (intended and estimated). Each mean of these factors was shown in Appendix. Table 1 shows Pearson's coefficients of correlation among these factors.

**Self-accuracy and Others-accuracy** Self-accuracy was positively correlated with the other three psychological factors: others-accuracy, anxiety, and importance ( $r = 0.62$ ,  $0.64$ ,  $0.80$ ,  $p < .001$ , respectively) in the rumor condition. In the criticism condition, it was positively correlated with others-accuracy and importance ( $r = 0.79$ ,  $0.73$ ,  $p < .001$ , respectively), while it was not significantly correlated with anxiety. The relationships between others-accuracy with the other factors showed the same pattern as self-accuracy.

In order to examine the relationship between self-accuracy and others-accuracy in detail, we performed a repeated-measures ANOVA on accuracy rate as the dependent variable, familiarity (familiar vs. unfamiliar) as the between subject factor, tweet type (rumor vs. criticism), and accuracy (self vs. others), as the within-subject factors. All three main effects were significant ( $F(1, 796) = 24.7$ ,  $21.7$ ,  $70.3$ , respectively,  $p < .001$ ): The familiar condition ( $M = 4.8$ ,  $SD = 1.7$ ) were more accurate than the unfamiliar condition ( $M = 4.2$ ,  $SD = 1.7$ ), the criticism condition ( $M = 4.7$ ,  $SD = 1.5$ ) were more accurate than the rumor condition ( $M = 3.9$ ,  $SD = 1.7$ ), and others-accuracy ( $M = 4.6$ ,  $SD = 1.4$ ) was higher than self-accuracy ( $M = 4.0$ ,  $SD = 1.8$ ).

The interaction between tweet type and accuracy was also significant ( $F(1, 796) = 66.3$ ,  $p < .001$ , Figure 2). Simple main effect of tweet type was significant only on self-accuracy ( $F(1, 1592) = 61.7$ ,  $p < .001$ ): The rumor condition ( $M = 3.4$ ,  $SD = 1.8$ ) was less accurate than the criticism condition ( $M = 4.7$ ,  $SD = 1.7$ ). Simple main effect of accuracy was significant only on rumor tweet ( $F(1, 796) = 136.6$ ,  $p < .001$ ): Self-accuracy ( $M = 3.4$ ,  $SD = 1.7$ ) was lower than others-accuracy ( $M = 4.5$ ,  $SD = 1.5$ ).

These results show that participants evaluated rumor tweets less accurately than criticism tweets; however, they estimated that others would evaluate rumor tweets as accurate as criticism tweets. This result indicates that participants think that they can detect unreliability of a

rumor tweet but that others cannot. There is a tendency for participants to underestimate the ability of others to evaluate accuracy of a rumor.

Figure 2: The analysis revealed that the bar of self-accuracy in the rumor condition was lower than the other three bars. Each bar shows the mean of 40 participants and 10 tweets. Error bars represent standard errors.

**Anxiety** The means of anxiety in the rumor and the criticism conditions were  $4.0$  ( $SD = 1.9$ ) and  $3.0$  ( $SD = 1.8$ ), respectively. In the rumor condition, anxiety was positively correlated with self-accuracy, others-accuracy, and importance ( $r = 0.64$ ,  $0.35$ ,  $0.71$ ,  $p < .001$ ,  $p = 0.05$ ,  $p < .001$ , respectively). On the other hand, anxiety was positively correlated with importance ( $r = 0.57$ ,  $p < .001$ ) in the criticism condition, while there was no correlation between anxiety and any accuracy. Thus, we found that the more accurate participants perceived rumors were, the more anxious they became. In contrast, anxiety was not correlated with accuracy in criticism tweet. In other words, if a tweet adopts a writing style in which it criticizes other tweet, participants' perceived accuracy of the tweet does not influence anxiety.

The inconsistency in accuracy and anxiety between the present study and past studies may be due to the differences in the measurement of transmission. An index to measure rumor transmission used in many studies was proportion assessed by dividing the number of rumor passed along by the number of rumor heard (e.g., Rosnow, et al., 1986; Rosnow, et al., 1988; DiFonzo & Bordia, 2000). By contrast, in the present work, the transmission was measured by asking to how many people a participant intended to transmit a rumor.

**Importance** The means of importance in the rumor condition and the criticism condition were 4.0 ( $SD = 1.9$ ) and 4.3 ( $SD = 1.9$ ), respectively. Importance was positively correlated with the other three psychological factors. It was also positively correlated with intended transmission in the rumor condition ( $r = 0.32, p = 0.04$ ). On the other hand, there was no significant correlation in criticism tweet.

**Intended and Estimated Transmission** Intended transmission was correlated with no psychological factors except for importance in the rumor condition. Estimated transmission was not correlated with any psychological factors. It was positively correlated only with intended transmission in both the rumor condition and the criticism condition ( $r = 0.31, 0.47, p = 0.05, 0.002$ , respectively).

The nonsignificant relationship between anxiety and rumor transmission is inconsistent with the past finding that anxiety was related to rumor spread (e.g., Anthony, 1992; Jaeger, et al., 1980; Prasad, 1935; Pezzo & Beckstead, 2006; Rosnow, et al., 1988; Walker and Beckerle, 1987). As the mean anxiety of rumor in this study was approximately at the center of the 7-point scale, it would be unlikely that we observed a floor or ceiling effect as Pezzo & Beckstead (2006) pointed out.

Of all psychological factors examined in the current study, importance was the only factor that was related to rumor transmission. The more important participants evaluated a rumor, the more they intended to transmit it. This result is congruent with the past studies showing that a positive relationship of importance to transmission (see DiFonzo & Bordia, 2007). Unlike the past work, in which the relationship between importance and transmission did not reach statistical significance (e.g.,  $r = 0.12, p > 0.30$  in Rosnow et al., 1988), the current study found a strong relationship between importance and transmission. This relationship was found only in intended transmission, but not in estimated transmission. Thus, participants distinguished these two questions of transmission; subjective importance of rumor had an effect on subjective intention of transmission, not on expected behavior of others.

### Rumors vs. Criticisms

A tweet type (rumor vs. criticism) by transmission (intended vs. estimated) analysis of variance was conducted, with means of 10 tweets (Table 2) in each tweet type as a dependent variable. The main effect of transmission was significant,  $F(1, 40) = 16.7, p < .001$ : Intended transmission was higher than estimated transmission. The main effect of tweet type and interaction between two factors did not reach statistical significance. This is, we think, because familiarity in both rumor and criticism was very low. Approximately only 16% of participants were familiar with the tweets. Most tweets were new to participants, and, thus, they estimated that a tweet had not been spread as much as they wanted to transmit it.

As a next step, each response of intended transmission and estimated transmission was classified into two conditions according to importance rate: low importance (1

to 4) and high importance (5 to 7). We performed this classification in the rumor condition and the criticism condition separately. There was no main effect of tweet type on intended transmission as the dependent variable by analysis of variance (ANOVA), with tweet type (rumor vs. criticism) and importance (high vs. low) as the between subject variables,  $F(1, 779) = 0.6, p = 0.4$ , while the main effect of tweet type was significant on estimated transmission as the dependent variable,  $F(1, 717) = 38.0, p < .001$ : Estimated transmission rates in the criticism condition ( $M = 1,036,225.4, SD = 2,789,937.5$ ) were higher than the rumor condition ( $M = 115,900.4, SD = 284,913.2$ ).

Table 2: Means and standard deviations for intended transmission and estimated transmission in the rumor condition and the criticism condition.

	Intended transmission		Estimated transmission	
	Rumor	Criticism	Rumor	Criticism
Mean	8,451,611	10,414,968	123,811	1,125,707
(SD)	(13,242,046)	(18,640,311)	(121,392)	(1,815,517)

Note. Each mean is of 40 participants.

Figure 3: There was no significant difference between rumors and criticisms on intended transmission, while the two-way ANOVA on estimated transmission revealed the interaction between tweet type and importance. Error bars represent standard errors.

The interaction between tweet type and importance was also significant on estimated transmission  $F(1, 717) = 8.3, p = .004$  (see right four bars in Figure 3). The simple main effect of importance was significant only in the criticism condition,  $F(1, 375) = 10.4, p = 0.001$ : Estimated transmission rate of the criticism condition was higher in

high importance condition ( $M = 1,455,451.9$ ,  $SD = 3,250,638.1$ ) than low importance condition ( $M = 536,565.9$ ,  $SD = 2,011,841.9$ ). There was no significant difference in estimated transmission of the rumor condition between high and low importance conditions. The simple main effect of importance was significant on intended and estimated transmission,  $F(1, 779) = 62.3$ ,  $F(1, 717) = 11.4$ ,  $p < .001$ , respectively: transmission rate in importance high condition (Intended transmission:  $M = 144,816.0$ ,  $SD = 312,746.4$ , Estimated transmission:  $M = 1,455,451.9$ ,  $SD = 3,250,638.1$ ) was higher than importance low condition (Intended transmission:  $M = 94,578.9$ ,  $SD = 261,279.8$ , Estimated transmission:  $M = 536,565.9$ ,  $SD = 2,011,841.9$ ).

In intended transmission, there was no significant difference between rumor and criticism tweet. Regardless of tweet type, the more important a tweet was, the higher the participants' intended transmission was. This result shows a simple relationship between importance and intended transmission. On the other hand, importance had an effect on estimated transmission by interacting with tweet type. While the degree of importance of rumor tweets did not influence on estimated transmission, that of criticism tweets did influence on estimated transmission; the more important a criticism tweet was, the higher the participants' estimated transmission was. These results show a discrepancy between intended and estimated transmissions in terms of tweet type. If people actually could transmit rumor and criticism as they intended, rumor and criticism should be spread at the same rate in Twitter. Thus, they should estimate a similar pattern of transmission of rumor and criticism. However, participants estimated that important criticisms were more spread than important rumors. This may imply that estimated transmission, in the present study, reflects participants' wish that criticisms should be shared more than rumors.

With regard to criticism tweet, it was operationally defined, in the current study, as a tweet that criticized a rumor tweet by citing it. While accuracy of rumor was correlated to anxiety, accuracy of criticisms was not correlated to anxiety. This result indicates that accuracy of a criticism does not increase anxiety. One interpretation is that the perceived accuracy of criticisms reduces anxiety compared to rumors. Similarly, Bordis, DiFonzo, & Haines (2005) showed that rumor denials reduced anxiety by interacting with personal relevance and source credibility.

Besides, criticism tweets were evaluated more accurate and more important than rumor tweets. There are two important points here. First, approximately 90% participants were unfamiliar with the criticisms on average. Second, participants were not given any strong evidence to show that each criticism was truthful. Based on the definition of rumor (DiFonzo & Bordia, 2007, p.13), the criticisms presented in the current study are also considered a kind of rumor. In this perspective, the difference between a criticism tweet and a rumor tweet in this study was whether it adopts criticizing form citing an original tweet. Why were criticism tweets evaluated as more accurate and more important than rumor

tweets? One possible explanation is that, if a tweet has a criticizing form citing an original tweet, the accuracy and importance of the criticizing content are raised relatively to the accuracy and importance of the cited original tweet.

## Limitation and Future Research

The measurement of transmission is one limitation of this study. In terms of ethical consideration, tweet transmission was measured by asking intended and estimated transmission instead of measuring how participants actually spread tweets. The actual spread of tweet is also affected by the number of follower a user has. Thus, even if a participant intend to transmit a tweet to a few million people, if the user has only a few follower, the tweet will not be transmitted so much. We need to pay attention to the difference between intended or estimated transmission and actual transmission.

The order of rumor tweet and criticism tweet was fixed in the current study: All participants were given rumor tweets first, and then criticism tweets. Thus, the possibility, which responses to criticism tweets were influenced by the responses to rumor tweets, was not excluded. What if we receive criticism tweets first? Do psychological responses to criticisms help minimizing the spread of false rumor? Further research is needed to examine this possibility by comparing the experiment presented in the present study as a condition with another conditions with the different order of rumors and criticisms.

## Conclusions

The major contributions of the present study were (1) to reveal the relationship between psychological factors and information transmission using real tweets posted after the earthquake; and (2) to compare rumor tweet and criticism tweet. As a general conclusion, perceived importance seems to be a main predictor of tweet transmission. Better understanding of users' behavior through continued work in this area can help the design and use of social media systems, which in turn will help minimize the spread of false information during disasters, and enhance people's social media literacy.

## Abstract

The paper applies a limited version of the resources of Ontological Semantic Technology to the descriptions of animals in the American Heritage First Dictionary and constructs a partial ontology from them. The explicitly mentioned properties in the descriptions are then supplemented by common-sense knowledge that the descriptions assume available to their young readership, and the output is compared to the previous one. The results, albeit modest, shed some interesting light on the most similar and dissimilar pairs of animals, as described in text.

**Keywords:** common-sense knowledge; Ontological Semantic Technology; children's dictionary; animal dataset; similarity.

## Introduction

The paper explores the common-sense knowledge that is necessary to fully understand the definitions/descriptions (henceforth, just descriptions) of around 100 animals in the 2007 edition of the American Heritage First Dictionary (AHFD 2007) aimed at children in grades K-2 (ages 5-8). It does not address common-sense reasoning. The purpose is to get a grasp on how implicit information affects the structure of perceived knowledge, in this case of animal descriptions, and similarity among entities.

The AHFD contains about 2,000 entries, claimed, almost entirely correctly, to be written with a controlled vocabulary so that that every description contains only words that also have entries in the dictionary. What is challenging in this design for our task is the possible implication of self-sufficiency, that is, of a much reduced dependency on the child's knowledge of the world, unstated explicitly in the natural language descriptions but (unconsciously) assumed to be present for full comprehension.

Most AFHD definitions for animals follow the "genus proximum, differentia specifica" format that is common for dictionaries, in particular for the classification of animal species: "Goldfish is a kind of *fish* [genus]. Goldfish are usually *small* and *orange* [differentia]." Apart from the differentiating specifics (small, orange) and the few properties that are specifics for the genus (in the AHFD, fish

live in water, have tails, can swim well) and are thus inherited, the remaining knowledge necessary to understand such definitions remains implicit, because it is presumed to be common-sense of different kinds. There is, for example, no mention of a fish's gills or fins.

Capturing common-sense knowledge is a daunting task. We are assuming that descriptions of the (animal) world of this dictionary requires less common-sense knowledge simply because this world is more restricted than that of an adult and the dictionary was obviously designed to accommodate that. If that is so, then getting a grasp of that knowledge may be more feasible than in case of a common, unlimited, adult-level natural language communication<sup>1</sup>.

The goal is, then, to illustrate how much information is lost when common-sense knowledge is not made explicit. Using the methods of computational semantics, specifically our Ontological Semantic Technology, we are taking advantage of the unique design of the dictionary to identify the required common-sense knowledge for a reasonably full comprehension of its animal descriptions. In this way, we aim to get a sense of its common-sense knowledge dependency. As a result, we also hope to clarify some issues concerning the very nature of common-sense knowledge and the feasibility of its computational acquisition and use, which is, as a matter of act, our primary and real concern.

In Section 1, we introduce the notions of 'hard' and 'soft' common-sense knowledge and explore its relation to underdetermination of reality by language and to saliency and, then, to ontology and natural language meaning, contingency, and instantiation.. In Section 2, we will briefly survey pertinent prior work. Section 3 will sketch out the Ontological Semantic Technology, our research tool as we applied it to the material. Section 4 compares the worldview on the animals that the descriptions define with the one complemented by the common-sense knowledge necessary to understand them. Section 5 discusses the results,

---

<sup>1</sup> The distinction between children as "novices" who know less about many domains than "expert" adults is well established (e.g., Carey 1985)-for better or worse.

identifies the strengths and weaknesses of our approach, and discusses the future lines of research.

## Kinds of Common-Sense Knowledge

### Hard and Soft Common-Sense Knowledge

We are introducing this new pair of terms to differentiate between two kinds of common-sense knowledge that a reader of the AHFD must possess to fully comprehend a description. If that reader does not understand a word in the description and that word has its own AHFD entry, he or she may access the required knowledge from that entry, where it is explicitly stated. So, from the point of the initial entry, this information is implied but from the point of the dictionary, it is explicitly stated. We call this information the ‘soft common-sense knowledge.’ If, on the contrary, some information that is needed for a full comprehension of the entry is not stated explicitly anywhere in the dictionary, we refer to it as the ‘hard common-sense knowledge.’ The paper focuses on the latter.

Starting with the randomly selected AHFD description of *snake*, we line up (see graph in [http://web.ics.purdue.edu/~vraskin/snake\\_new\\_label.pdf](http://web.ics.purdue.edu/~vraskin/snake_new_label.pdf)) the lexical chains underlying the entry dependency: if entry  $E(x)$  uses word  $y$  in the description of word  $x$ , and  $y$  is not previously mentioned in the chain,  $E(x)$  leads to  $E(y)$ . If  $E(i)$  does not evoke any new words in its description, it becomes a terminal in the dependency line. The longest, 10-node dependency line holds, starting with the topmost leftmost node and ending with the rightmost node at the bottom of the picture: SNAKE is-a REPTILE is-a ANIMAL is-a-not PLANT agent-of MAKE has-agent BEE agent-of FILL result-in FULL precondition-of-not HOLD unspecified ROOM. What this perfectly representative branch illustrates is that there is no consistent or predictable semantic dependency in the chain and that the vagaries of lexicographic connection can traverse the domain of knowledge, common-sense and other, in all directions, with some connections not easily explained.

Altogether, the knowledge required to understand every word in the description of *snake* as well as every word in the descriptions of those words, and, in turn, every word in the descriptions of those words, and so on to the end of the chain, is expressed in 86 entries. Realistically speaking, no 5-year-old will read all the entries: much more likely, they will have the requisite knowledge of the words. Nevertheless, this information is made available by the AHFD compilers, perhaps similarly to the glosses, footnotes, and explanatory appendices in adult-level materials. Its availability makes it not quite common-sense knowledge—so we refer to this explicit, but remote information, as weak common-sense knowledge.

### Underdetermination and Saliency

It is known that language underdetermines reality (see, for instance, Barwise and Perry 1983; Nirenburg and Raskin 2004): no matter how fine-grained or verbose the description of an event, there will be tons of details about

the situation that will remain unmentioned. If two men walk into the room, a report of that may include what they look like, what they wear, the speed of their movement, etc. But it will mention nothing about their places of birth, parents’ names and occupations, what cars they drive, what they had for breakfast, etc.

Now, all that knowledge exists, and common-sense knowledge includes that these people have a birth place, have parents, likely drive cars (especially if they’re Americans), etc. What is essential, however, is that most of the existing but implicit information is not prominent: much more likely, the prominence goes with the purpose of those people’s entrance into the room, whether there is any cause for alarm or displeasure, etc. The amount of prominent, or salient common-sense knowledge is much more limited in any situation.

Unfortunately, saliency (see Giora 2003: 13-38 and references there) is dynamic and fluctuates very rapidly. In AHFD, however, saliency may be conveniently seen as deliberately delimited by the availability of entries for words, thus reflecting the compilers’ notion of the mental model for a five-year-old’s world.

### Instantiation and contingency

In Ontological Semantic Technology (OST), the ontology consists of concepts and relations between them that are determined by properties. The concepts anchor lexical senses that are defined in the separate lexicon. Thus, one sense of the word *cat* is anchored in the ontological concept CAT. In a sentence, *A cat can jump from the floor to the top of a bookcase*, CAT is what the word *cat* means, i.e., a generic, any member of the class.

In the sentence, *Kisa the cat can jump from the floor to the top of a six-foot tall bookcase*, however, it is no longer a generic cat, but a specific instance of the concept, and the relationship between the meaning of the word *cat* and the ontological concept CAT is no longer that of generic anchoring. This instantiation makes the sentence contingent on a number of indices, such as the identities of the speaker and hearer, time, place, etc. (see Lewis 1972—cf. Bar Hillel’s 1954 comment on rare non-contingent sentences, such as, *Ice floats on water*).

We understand common-sense knowledge as non-contingent and involving concepts, not their instances. It is about what exists in the world, not what we know about particular objects or events. Our common-sense knowledge includes the fact that houses may be painted in various colors; it does not include the fact that Tom’s house is grey with burgundy trim.

So the common-sense knowledge left implicit by the AHFD is strong, non-contingent, and definitely less salient than the knowledge explicitly supplied by the AHFD in its descriptions.

## Prior Pertinent Work on Common-Sense Knowledge

Distinguishing common-sense knowledge from other implicit types of knowledge has been an issue in approaches to knowledge engineering, and while it always is a central one, it often remains implicit. Knowledge-based NLP has (re-)matured enough both to be able to need as well as to accommodate the type of “deep” knowledge that overlaps with the varying notions of common sense.

McCarthy (1959) is often cited as the earliest mention of common sense in the literature, but Bar-Hillel’s (1954) well-known example, “Little John played in his pen,” is already a clear indication of the necessity and importance of the common-sense knowledge—in this case, about relative sizes of objects.

Prominently, Lenat (1990) started an early large-scale systematic project on acquisition of common-sense knowledge, CyC. His method was hand-coding by a large number of research engineers, with a high turnaround and no well-defined acquisition methodology, which affected results and rendered them unusable for the NLP community.

Gordon and Schubert’s overview (2010) classifies current approaches to common-sense knowledge acquisition as: hand-authoring of rules, as in CyC; abstracting from clusters of propositions (e.g., Van Durme 2009); and directly interpreting general statements, such as glosses in dictionaries (e.g., Clark et al. 2008), akin to the approach of the present paper. Other researchers have used tagging, annotating, and/or generic machine learning techniques for automatically extracting implied common-sense knowledge from explicit text on the Web, about which Lin et al. (2004) have legitimate reservations, because explicit statements on the Web do not necessarily express common-sense knowledge.

Finally, we need to mention the area of research on common sense dedicated to children’s development of such knowledge, not least related to their overall linguistic-cognitive development. In particular, children’s knowledge about animals is one of the applications. Results that inform our present approach include that children focus on external features rather than internal organs, on habitats, on behavior relevant for humans (dangerous, edible) rather than cladistic accuracy (“Is a camel an ungulate?”), and that children’s knowledge is derived from observations as much as instructions, parents, or media (see Prokop et al. (2007), Tunnicliffe et al. (2007), Byrne et al. (2010)).

In our own previous work (Taylor et al. 2011a), we include in the common-sense knowledge rules of a separate resource the knowledge-of-the-world information that is not already contained in the ontology and lexicon (see next section). In the experiment there, we processed text with our system, and as part of routine quality assurance, added the necessary common-sense knowledge wherever we failed to interpret the text correctly because of the unavailability of this information in our resources (after we have excluded other, more banal reasons for the failure, such as an error in the resources or a bug in the software). Thus, we identified

as missing, for example, size classes necessary to understand spatial relations between physical objects, such as the understanding that a containing object should have greater dimensions than the (solid) object it contains.

In contrast to previous work, which addressed the identification and acquisition of common-sense knowledge by OST for the general purpose of processing text, this paper applies an appropriately limited version of our resources to a very limited corpus of a specific genre in an attempt to compare the ontological information following from the AHFD descriptions only with the ontological information arising from the descriptions supplemented by the common-sense knowledge that the descriptions imply in their readership.

## Brief Introduction to OST

Charniak’s (1972) often (mis)cited children’s story is used primarily to discuss inferencing and, hence, reasoning. It is even more suitable for exemplifying (in square brackets) the most common common-sense knowledge that OST has to deal with in order to fulfill its function of representing the meaning of natural language text accurately and comprehensively.

*Jane was invited to Jack’s birthday party.* [One brings presents to a birthday party. Presents are often purchased. To purchase something, one needs money.] *She wondered if he would like a kite.* *She went into her room and shook her piggy bank.* [Piggy banks contains money, usually coins. Coins make noise when shaken] *It made no sound.* [Coins make noise.] → (either there was no money in the piggy bank or just no coins but rather bills → in the former case, Jane may have lacked the money to buy the present)].

The italicized part is the original story; our formulation of the common-sense knowledge is in square brackets; the parenthesized part following the first arrow represents our formulation of inferences in reasoning, and while definitely pertinent to common-sense knowledge, it will be left out of this paper. It is noteworthy that the reasoning statements are contingent on the story while common-sense knowledge is generic.

The first and essential function of OST is to interpret the text of the story. The OST processor reads each sentence linearly and looks it up, word by word, in the OST English lexicon. Every sense of every (non-auxiliary, non-parametric) word in the lexicon is anchored in an ontological concept, with its properties and fillers, and the fillers can be restricted by the sense. The OST ontology, unlike its lexicons, is language-independent (see Nirenburg and Raskin 2004 for the basic theory of Ontological Semantics, and Raskin et al. 2010, Hempelmann et al. 2010, Taylor and Raskin 2011, Taylor et al. 2010, 2011a,b, for the much revised OST).

To use a greatly simplified example, the sense of the English word *invite* will be anchored in the ontological concept, probably also labeled “INVITE.” The label does not contain any but distinguishing information for the computer

and can be any ASCII combination—it is there just for the convenience of the human acquirer.

INVITE		
is-a	communicative event	
agent	human	
beneficiary	human	
theme	social-gathering	
purpose	entertainment	
invite		
Invite		
agent	[preceding NP]	
beneficiary	[following NP]	
theme	[to NP]	
...		

And the text meaning representation (TMR) of the first sentence of the story will result from matching the meaning of the NPs in the appropriate EVENT slots. The reality is, of course, harder, with more complex syntax, ambiguity, etc. The unenhanced-OST problem with the story is still more advanced: while TMR for each sentence is not hard to produce, the system will not be able to relate the sentences to each other, and the text will lack cohesiveness.

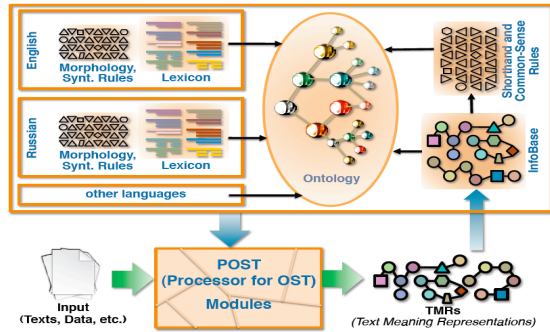

Figure 1: OST Architecture

In OST, the information processed prior to computing the TMR of the current sentence is used to clarify, complement, and disambiguate the current representation process. In this case, that information would be helpless and useless because, other than Jane as the agent, no previous sentence in the story even mentions objects in the following sentences, and it is the common objects (or events) that the anaphora/coreference resolution establishes as bridges between and among sentences. Jane will emerge from the story, as interpreted by the unenhanced OST, as performing three unrelated actions. It is the common-sense knowledge statements in the square brackets above that have to provide such common objects to make OST processing possible: the bridge words are underlined in the story above., and the common-sense knowledge enhanced text can be processed by OST normally.

This is why we recently added to the OST architecture (Figure 1 above) the common-sense knowledge resource (Taylor et al. 2011a) and the methodology of adding to it when the TMRs fall short of the (often hypothetical) gold standard (cf. Allen et al. 2008).

## Ontology of Descriptions and Ontology With Common-Sense Knowledge

In general, we are interested not only in reading and understanding a text, but also in structuring information that this text contains, as well as enhancing our ontology when newly acquired information requires. We are using information about animals from AHFD to see whether such task is possible. We then check whether supplying additional information (common-sense knowledge left implicit in the dictionary) would help with the task (cf. Perfors et al. 2005; Kemp et al. 2006).

Typically, a hierarchy is perceived as one of the most important properties in ontology construction. All animal descriptions of the dictionary provide such information. Unfortunately, sometimes a word is used that may have multiple senses (such as *cat* being a domestic cat or feline) thus creating a flawed hierarchy. One of the goals, then, is to identify such descriptions.

The proposed measure is conditional on an accepted membership assumption. If we assume the veracity of “B is A” as a reference point, which gives us a certain amount of knowledge about B in terms of its properties, we estimate the extent to which “C is B” is (dis)confirmed as

$$\frac{\sum_i 2^{-n} * w * hier_{P_i(C,B)}}{num(i)} \text{ where } w \text{ is a property weight, and}$$

$$hier_{P_i(C,B)} = \begin{cases} 1, P.b \in D_B \text{ \& } P.c \in D_C \text{ \& } b = c \\ -1, P.b \in D_B \text{ \& } P.c \in D_C \text{ \& } b \neq c \\ 0.1, P \in D_C \text{ \& } P \notin D_B \\ 0, \text{ otherwise} \end{cases}$$

Placement in the hierarchy as well as concepts’ properties (may) affect similarity between concepts. For the purposes of this paper, we assumed that the properties that are taken into account are all equally weighted. We measure similarity

of two concepts as  $\frac{\sum_i 2^{-n} * w * sim_{P_i(A,B)}}{num(i)}$  where  $sim_{P_i(A,B)}$  is

defined as:

$$sim_{P_i(A,B)} = \begin{cases} 1, P.a \in D_A \text{ \& } P.b \in D_B \text{ \& } a = b \\ -1, P.a \in D_A \text{ \& } P.b \in D_B \text{ \& } a \neq b \\ 0.1, P \in D_A \text{ \& } P \notin D_B \text{ \& } P \notin D_A \text{ \& } P \in D_B \\ 0, \text{ otherwise} \end{cases}$$

## Results and Conclusion

We first wanted to see what kind of structure we would get from the descriptions without the use of common sense. We calculated pair-wise similarity measurements for all animals with AHFD descriptions. The similarities ranged from -1.25 to 0.78. It is possible for the similarity to be -N where N is the number of properties in both descriptions and all properties in the descriptions match but their fillers do not. Having calculated the mean and standard deviation, we looked at the results that were at least 3 standard deviations away from the mean as most similar cases and most dissimilar ones. The dissimilar pairs were: ant/chicken, ant/crocodile, ant/pony, ant/whale, bee/chicken, beetle/chicken,

bug/chicken, bug/shark, bug/whale, butterfly/chicken, caterpillar/chicken, caterpillar/crow, caterpillar/whale, chicken/cricket, chicken/fly, chicken/mosquito, chicken/moth, chicken/whale, cricket/whale, crocodile/whale, mosquito/whale, moth/shark, moth/whale, turtle/whale.

It should be noted that, with the exception of the chicken/whale, turtle/whale, and crocodile/whale pairs, the dissimilar pairs contain insects. One member of the pair is (typically) a bird or a mammal that is somehow different from the rest of its class, thus deserves an explicit clarification, such as a whale being a mammal. For some reason, insects also received a fairly large amount of description and thus were easy to contrast with other animals.

The similar pairs are: ape/monkey, bear/panda, bee/moth, beetle/butterfly, beetle/cricket, beetle/fly, bug/caterpillar, butterfly/cricket, butterfly/fly, camel/giraffe, caterpillar/cricket, caterpillar/moth, cricket/fly, donkey/zebra, eagle/hawk, fox/wolf, goose/turkey, horse/pony, leopard/lion, lion/tiger. Again, (an expected) a pattern can be noticed here: those animals that received a lot of similar descriptions are being selected.

There were 7 animals or categories in the dictionary that were used in the is-a relations other than to indicate an offspring of an animal. These categories were: animal, insect, bird, fish, reptile, cat, and horse. Mammal got an entry in the dictionary but was not used in any of the descriptions. We excluded entries that indicated *a young animal*, such as *a kitten is a young cat*. We calculated the mean and standard deviation of each animal relative to the above 7 categories using the *hier* metric described above. We assumed that if an entry had a description that X is Y, and  $\text{hier}(X, Y)$  was lower than the mean for that overall category, the definition should be questioned and should not be used for hierarchy construction. The following entries were so affected: bat is-a animal, crab is-a animal, goat is-a animal, hippo is-a animal, sheep is-a animal, whale is-a animal, ostrich is-a bird, tiger is-a cat, lion is-a cat.

There are several explanations for the results: cat is defined as a domestic animal, and thus, of course, cannot be a parent of wild animals. Crab has more features that puts it next to fish, and so does whale, including the description of the habitat. Hippo is mostly described swimming in lakes and rivers. Bat is similar in its description to a bird. Goat and sheep created a puzzle for us. However, we considered it to be a success to have only 2 problematic entries.

Interestingly, contradicting the dictionary, the metric suggests that donkey and zebra should be types of horse; dog and hamster should be types of cat. These entries suggest that there is not enough differentiation between the affected animals for them to be correctly classified.

We therefore wanted to see if the ratio changes when the omitted common-sense knowledge is added to the descriptions and if some puzzling results are corrected. The common-sense knowledge consisted of a number of additional animal properties, explicitly stated in some

descriptions but omitted from others, with clearly implied values, so we added that information directly to the ontology as it emerged from the descriptions. The addition to common-sense knowledge solved the hierarchy problem of animal in the previous experiment not being an animal, and did not introduce any additional problems.

The distribution of the resulting similarity is shown in Figure 2. As seen there, listing results that are 3 standard deviations away from the mean proved to be impractical, although that was done in the first experiment,. Thus, the results below reflect the same number of dissimilar pairs as the first experiment: ape/duck, ape/swan, duck/snail, crocodile/snail, chicken/snail, crow/snail, alligator/snail, ape/goose, beaver/snail, eagle/snail, hawk/snail, goose/monkey, fox/snail, hamster/snail, duck/monkey, ape/snail, deer/swan, ape/crab, goose/snail, camel/snail, jellyfish/monkey, ape/penguin, bear/snail, goat/snail. As with previous results, there is a concept that is most dissimilar to others (snail), and the dissimilarity looks plausible (all below 0).

Figure 2. Distribution of similarity of animals

The pairs that are most similar are again several insects and birds, as well as eagle/hawk, crab/lobster, hippo/rhinoceros, bull/cow, dolphin/whale, horse/pony, cow/sheep, cow/pony, cow/sheep, frog/toad, pig/pony, lion/tiger, mouse/rat, jellyfish/octopus, donkey/zebra, spider/worm. As expected, the similarity results look (more?) reasonable with common-sense knowledge (Figure 3).

Figure 3: Pair-wise similarity of 7 animals.

While the most similar and least similar results look good, the middle section will need to be improved. Figure 4 shows pair-wise comparisons of perceived similarity between cow, dolphin, elephant, horse, mouse, rhino, seal, and squirrel. We anticipate these results to improve when weights are added to properties.

## Conclusion

We have demonstrated, on a very limited corpus of animal descriptions intended for a very young audience, that it is possible to detect semantic structure in natural language descriptions as well as pointing to flawed descriptions. The results improve with the addition of common-sense knowledge omitted from but implied by the descriptions. The specific material, from a children's dictionary that was designed to limit the amount of world knowledge that the young reader could be counted on contributing, helped us delimit the common-sense knowledge. It is clear, of course, that this method of defining this elusive resource is not useful outside of this artificially restricted environment but the convenient handle to it was too tempting to resist.

## Abstract

In comprehension of the metaphor “*TOPIC is VEHICLE*,” emergent features in the interpretation of metaphors are characteristic neither of the topic nor the vehicle. An experiment examines the hypothesis that new features emerge as metaphoric interpretations through association with non-emergent features connected with the topic, vehicle, or both. In the experiment, participants were presented with a non-emergent feature as a prime, a metaphor, and an emergent feature, sequentially. Participants were then asked to respond as to whether the emergent feature is an appropriate interpretation of the metaphor. The results showed that primed non-emergent features derived from the vehicle facilitate the recognition of emergent features. The results support an account in which new features emerge through two processes – non-emergent features are recognized as interpretations of the metaphor and then these non-emergent features facilitate the recognition of emergent features. **Keywords:** Metaphor comprehension; Feature emergence; Interaction.

## Introduction

In this research, we examined the process of feature emergence, which is realized in comprehension of metaphors taking the form of “*TOPIC is VEHICLE*”, such as “Education is a gateway.” In previous papers, interpretations (features) of this kind of metaphor were classified into four types: common features, topic features, vehicle features and emergent features (Becker 1997; Gineste, Indurkha & Scart, 2000; Nueckles & Janetzko 1997). When an interpretation is thought of in relation to both the topic and the vehicle, it is regarded as a common feature. When an interpretation is thought of as a characteristic of the topic (or of the vehicle), it is referred to as a topic feature (or a vehicle feature). The common, topic and vehicle features are regarded as non-emergent features. Finally, emergent features are not typically thought of in relation to either the topic or the vehicle alone, but do come to mind when the topic and vehicle enter into a metaphoric comparison. For example, for the metaphor “Ideas are diamonds,” the feature “come in a flash” is a topic feature, “beautiful” is a vehicle feature, “precious” is a common feature because it is listed as a feature when people are given either “ideas” or “diamonds” by themselves, and “unique” is an emergent feature because it is not listed for either word by itself, but is listed when the words are paired.

Previous research (Gineste et al., 2000) made a list of features and reported that over 60% of metaphoric interpretations are emergent features. Emergent features are thus

prevalent and play an important role in metaphor comprehension. Furthermore, the authors conducted an experiment using priming effects. In their experiment, emergent, topic-term or vehicle-term features were presented and participants judged whether the feature was related to the primed metaphor (topic-/vehicle-term) or not. Emergent features required a longer response time to be regarded as a feature of the prime than topic or vehicle features, when the features were tested with topic-term or vehicle-term primes. When tested with the metaphor as the prime, the topic and vehicle features required longer response times than did the topic-term or vehicle-term as the prime. However, the emergent features did not change their response times from one prime condition to another. As a result of these results are consistent with the interaction theory of metaphor (Black 1979), which suggests that metaphor comprehension is a product of an interaction between the target and the vehicle concepts.

However, there is also evidence that links emergent interpretations asymmetrically with topics and vehicles. Becker listed interpretations of metaphors in an experiment. She reported that altering a metaphor’s vehicle (e.g. “A smile is a knife” vs. “A smile is a pearl”) produced greater changes in emergent content than did altering the topic (e.g. “A smile is a knife” vs. “Teeth are knives”). This suggests that emergent features are influenced primarily by one’s representation of the vehicle. Nueckles and Janetzko (1997) introduce the idea that metaphor comprehension proceeds in analysis-based and synthesis-based stages. According to their idea, there is first an analysis of the lexical meanings of the topic and vehicle during the analysis-based stage. If the topic and vehicle have sufficient similarity, the metaphor comprehension does not proceed to the synthesis-based stage. For cases in which the topic-vehicle similarity is not sufficiently high, a shift to synthesis-based processing occurs. In the later case, the metaphor comprehension is achieved through a construction of new components of meaning by synthesis of the topic and the vehicle. It is during this second phase that emergent features would be generated.

Previous computational models of metaphor comprehension have been constructed under the assumption that emergent features are emphasized more than non-emergent features through interactions among features in metaphor comprehension (Utsumi, 2000; Terai & Nakagawa 2007, 2008,

2010). All of these models function to increase activation of emergent features beyond that of non-emergent features by incorporating interactions among features. Terai and Goldstone (2011) reported that emergent features require more time to be recognized during a metaphoric interpretation than do non-emergent features. Conversely, when a relatively long time period was allowed for metaphor processing, then recognition of non-emergent features was diminished. This suggests that non-emergent features that are true of one metaphor term but not the other have reduced activation as metaphor processing continues. The results support the kind of positive and negative interaction among features assumed by the computational models above, and also supports Nueckles and Janetzko's (1997) two-process assumption. In particular, the meanings of the topic and the vehicle are emphasized as non-emergent features, and then with ongoing interactions among features, emergent features are discovered as valid interpretations. However, empirical evidence is still lacking to support the details of this mechanism.

Some previous research used a priming paradigm to investigate the roles played by the topic and the vehicle in metaphor comprehension and reported that metaphor comprehension was facilitated by presentation of either a vehicle or topic concept (Wolff & Gentner, 2000; McGlone & Manfredi, 2001). McGlone and Manfredi used a sentence ascribing a metaphor-irrelevant or metaphor-relevant property to a topic or a vehicle as a prime. They found that all of these presentations, including the presentation of the sentences ascribing metaphor-irrelevant properties to topics, facilitated metaphor comprehension with the exception of sentences ascribing metaphor-irrelevant properties to vehicles.

Thus, we conducted an experiment employing priming effects of non-emergent features (common, topic and vehicle features) in order to investigate the role played by these features in processing emergent features and test the two-process assumption of feature emergence. If the two-process assumption is correct, non-emergent features should activate emergent features. An unresolved issue concerns the kinds of non-emergent features that most influence activation of emergent features.

## Experiment Method

In this experiment, we examined the priming effect of non-emergent features on processing of emergent features in metaphor comprehension.

### Participants

134 undergraduates participated in this experiment. All participants were native English speakers.

### Materials

We selected 39 metaphors of the form "*TOPIC is VEHICLE*" from Becker (1997) as "target metaphors." Becker (1997) asked participants to list features of individual words and interpretations of metaphors involving those words. She categorized the resulting features into four types: emergent, com-

mon, topic, and vehicle features. Based on her categorization and feature listings, for each of these 39 metaphors, 1 to 4 emergent features and 1 to 4 non-emergent features were selected. 114 emergent features, 26 common features, 29 topic features and 32 vehicle features were selected. The types of the non-emergent features (common, topic or vehicle feature) selected for a given metaphor differed from each other. Three native English speakers checked these selected features to ascertain whether a feature and the word is an appropriate interpretation of the metaphor or not. For the selected items, at least one judge recognized the feature as an apt interpretation of the metaphor.

In addition, another 39 metaphors of the form "*TOPIC is VEHICLE*" from previous research (Gentner & Clement 1988, McGlone & Manfredi 2001) were used as "irrelevant metaphors" in a baseline condition.

### Procedures

The procedures are shown in Figure 1. In the prime condition, participants were first presented with a non-emergent feature as a prime on a screen for 2 seconds. In the no-prime condition, no prime was presented. In both conditions participants were then asked to interpret a metaphor that was presented on the screen for 3 seconds. After presentation of the metaphor, an emergent feature was presented as a target word. The participants were asked to respond "Yes" or "No" depending on whether the word was related to the metaphor or not. Participants responded by pressing the "p" key ("Yes") or "q" key ("No") within 6 seconds. They were asked to respond as fast as possible without sacrificing accuracy. If they could not respond within 6 seconds, the feature disappeared and the text "Your response is too slow" appeared on the screen. The fixation point was presented between trials. For each metaphor, the combination of the prime and emergent features was randomized. The target metaphor and baseline conditions were presented equally often, but the presentation frequencies of feature conditions were dependent on the number of features.

In order to distinguish between the relationship between just a prime (non-emergent features) and target words (emergent features) and the interaction between them in metaphor understanding, we used irrelevant metaphors as a baseline. For example, if presentation of the common feature "beautiful" as a prime for the metaphor "Stars are diamonds" facilitates recognition of the subsequent emergent feature "amazing," there are two possible cognitive mechanisms. One is that "beautiful" influences the metaphor understanding process and facilitates recognition of "amazing" as an interpretation of the metaphor. The other is that "amazing" directly relates to "beautiful" much in the same way that "doctor" is related to "nurse," and so presentation of "beautiful" facilitates "amazing" regardless of the metaphor understanding process. Thus, we also employed irrelevant metaphors as a baseline. If presentation of "beautiful" does not influence judgments of the interpretation of an irrelevant metaphor (e.g. "Crime is a disease") but does influence judgments of the related metaphor, then this will be taken as evidence that not only the

relationship between “beautiful” and “amazing” is relevant, but also the interaction between “beautiful” and “amazing” have a role in metaphor understanding. Therefore, in the target metaphor condition, prime and target words are listed as interpretations of an intervening target metaphor. In the baseline condition, an irrelevant metaphor is presented between prime and target words, which do not relate to it. Therefore, there were two conditions of metaphors (target metaphor and baseline conditions) and four conditions of primes (common, topic, and vehicle features, and no-prime). After all trials, participants were asked to evaluate aptness and conventionality of the metaphors on the scale of 1 (highly inappropriate or rare metaphor) to 5 (highly appropriate or common metaphor).

## Results

The data of two participants were removed because they responded “Yes” to more than half of the items in the baseline condition. We analyzed the remaining data obtained from 132 participants. The average rate at which the participants responded within the time limit was 99.4%.

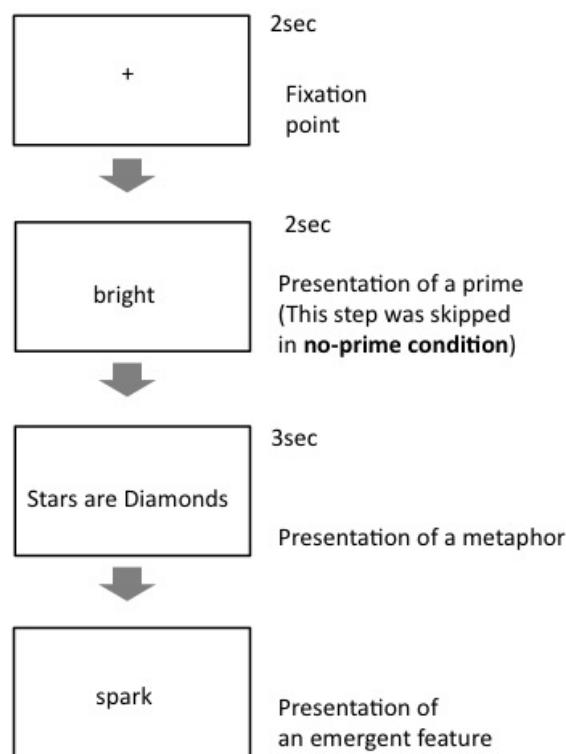

Figure 1: Time course of a trial in the experiment. In the target metaphor condition, prime and target words are interpretations of the metaphor which was presented between them. In the baseline condition, the primes and targets do not relate to the metaphor.

## Analysis of all data

The averages of response times are shown in Table 1. In the target metaphor condition, the response time is longer than in the baseline condition ( $F(1, 131) = 6.43, p < .05$ ). There is also a main effect of prime kind ( $F(3, 393) = 7.38, p < .01$ ). Combining across difference of kinds of prime and metaphor conditions, primes made participants respond faster. The results show that the prime facilitated responding to target words (emergent feature) and made judgment to them faster in both conditions. The results indicate that there is a relationship between a prime (non-emergent features) and target words (emergent features).

We analyzed the difference between response times depending on the response. Average response times when the participants respond “Yes” or “No” are shown in Table 2. Thirty participants responded “Yes” (“No”) for all emergent features with any kind of prime in the target metaphor condition (in the baseline condition) and these data were removed for this analysis. There was an interaction between metaphor condition and responses ( $F(1, 101) = 86.1, p < .01$ ). Participants responded “Yes” significantly faster than “No” in the target metaphor condition. Conversely, they responded “No” faster than “Yes” in the baseline condition. In the target metaphor condition, when participants responded “Yes,” the response is correct in the sense that the materials were designed so that the target would be an apt interpretation of the metaphor. Similarly, in the baseline condition, a “No” response would be correct. This suggests that people might be making errors not through fast guessing, but because of close competition between “Yes” and “No” responses. And, when participants made errors, there was a possibility that they could not interpret the metaphor. Thus, the response times confirmed an influence of the primes to “the correct responses.” So, we tested the “correct” responses.

## Analysis of correct responses

The average response times when the participants responded with the “correct” response are shown in Figure 2. The results show that the primed non-emergent features (common, topic, vehicle features) facilitated processing of emergent features ( $F(3, 393) = 8.12, p < .01$ ) in both conditions.

Therefore, we tested proportions of correct responses. The proportions of “Yes” responses in the target metaphor and “No” responses in the baseline condition are shown in Figure 3.

The proportions were analyzed using a two-way ANOVA<sup>1</sup>. The proportion of correct responses in the baseline condition is higher than in the target metaphor condition ( $F(1, 131) = 15.7, p < .01$ ). The response times and the accuracy rates indicate that it was more difficult to recognize an emergent feature as an interpretation of the metaphor than to find that

<sup>1</sup>When an arcsine transformation was applied to the proportion data because of the restriction of these data to a 0-1 range and the proportions were analyzed using a two-way ANOVA after transformation, the results show the same tendency that are indicated when the non-transformed proportions are analyzed.

Table 1: Averages of the response times (milliseconds) for all data. Standard deviations are shown in parentheses.

		Metaphor (condition)	
		Target metaphor (Target metaphor condition)	Irrelevant metaphor (Baseline condition)
Kinds of prime	Common feature	1769.0 (957.0)	1724.2 (905.4)
	Topic feature	1759.8 (933.1)	1716.5 (927.2)
	Vehicle feature	1756.6 (877.8)	1718.2 (908.6)
	No prime	1848.7 (952.2)	1797.5 (934.8)

Table 2: Averages of the response times (milliseconds) depending on their responses. Standard deviations are shown in parentheses.

		Target metaphor condition	
		Response	
		“Yes”	“No”
Kinds of prime	Common feature	1704.3 (914.2)	1919.8 (1035.2)
	Topic feature	1726.6 (922.3)	1830.2 (952.3)
	Vehicle feature	1701.3 (891.6)	1861.6 (983.3)
	No prime	1816.3 (929.9)	1921.0 (997.1)
		Baseline condition	
		Response	
		“Yes”	“No”
Kinds of primes	Common feature	1839.3 (1080.4)	1687.9 (840.0)
	Topic feature	1821.8 (1010.5)	1684.1 (830.3)
	Vehicle feature	1851.9 (1042.3)	1679.6 (862.6)
	No prime	1848.9 (1056.8)	1781.8 (894.1)

the emergent feature was not an interpretation of the irrelevant metaphor. Furthermore, there is a two-way interaction ( $F(3, 393) = 4.16, p < .01$ ). There are no significant differences among the proportions correct in the baseline condition, however, the accuracy with the vehicle primes is significantly lower than with the common primes or without a prime in the target metaphor condition at a  $p < .05$  level. This means that presentation of a non-emergent feature as a prime affected the metaphor understanding process and that vehicle primes inhibited recognition of emergent features as interpretations of the metaphor. The difference of the results in the two conditions suggests an interaction between non-emergent and emergent features in metaphor comprehension.

Furthermore, there is no significant difference between proportions of correct responses with and without a com-

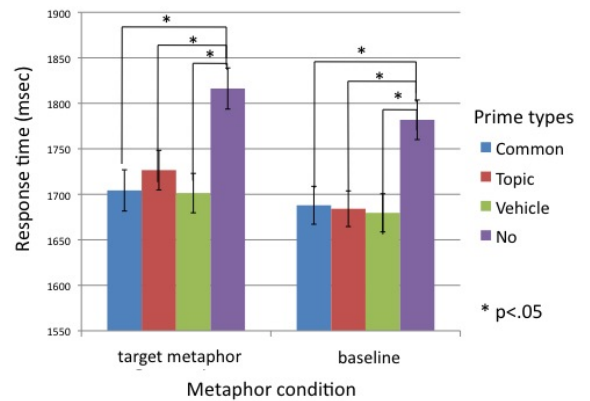

Figure 2: Average response times for correct responses. (The response time when they responded “Yes” in the target metaphor condition and when they responded “No” in the baseline condition.)

Figure 3: Average proportions of correct responses. (Average proportions of “Yes” responses in the target metaphor condition and that of “No” responses in the baseline condition.)

mon prime in the target metaphor condition. However, the proportion with common primes is slightly higher than without a prime. That is, the presentation of the common feature might make the emergent features recognized more easily as the metaphor interpretations.

## Discussion

The response time results show that participants gave faster correct responses with a prime than without a prime. Even in the baseline condition, the response times with a prime are shorter. Therefore, there is a robust relationship between the primed feature (non-emergent feature) and the target word (emergent feature), regardless of the condition. The proportions of correct responses with a vehicle prime were significantly lower than that with a common prime or with no prime in the metaphor condition but there was no significant difference in the baseline condition. The results of the proportion correct suggest the existence of an interaction between non-emergent and emergent features in metaphor comprehension.

McGlone and Manfredi (2001) found that the primed metaphor-irrelevant properties of vehicles inhibited metaphor comprehension. They concluded that metaphor-irrelevant property primes led their participants to initially consider the inappropriate literal sense of the vehicle, rather than retrieve the metaphoric category that the vehicle exemplified, their results are consistent with the interactive property attribution model (Glucksberg, McGlone, & Manfredi 1997). This latter approach models metaphor comprehension as a process of interpreting the topic as a member of the metaphoric category of the vehicle. This model can account for the inhibition of the emergent interpretation of the metaphor by presenting the vehicle feature prime. For example, the vehicle “gateway” can be interpreted either as a literal arch or as a metaphorical opening. If the vehicle prime “swings” is presented, this may be expected to inhibit the emergent metaphoric feature of “way to reach desired destination.” Our results provide evidence for active competition between literal and figurative interpretations of vehicles.

Particularly when a metaphor is not conventional, the metaphoric category of the vehicle may not simply be retrieved. For example, in the conventional metaphor “the lawyer is a shark,” the metaphoric category of “shark” (*e.g.* vicious, dangerous) may be stable and reliably activated. However, for the metaphor “marriage is a joyride,” because “joyride” is not only fun but also dangerous, the metaphoric category of “joyride” could be retrieved as a product of the features of either “fun” or “dangerous.” That is, the category of “joyride” might be unstable and flexibly represented. In this case, the presentation of a vehicle feature “fun” might inhibit the recognition of “frightening” which is associated with “dangerous.” In this experiment, the average rating of conventionality of the target metaphors is 2.74 (standard deviation is 1.73). Because this value is between 2 (slightly rare) and 3 (neutral), these metaphors should probably be considered non-conventional. As such, the priming of vehicle features could have inhibited recognition of the emergent features, many of which would not have been automatically triggered by the vehicle.

There was no significant difference between the proportions of correct responses with topic primes and without/with other primes in the metaphor condition. These results show

that features derived from the vehicle might affect feature emergence more than that from the topic, bearing in mind that the effect of vehicle features on the interpretation of emergent features is negative. This assumption is consistent with Becker’s (1997) suggestion that altering a metaphor’s vehicle produced greater changes in emergent content than did altering the topic.

The proportion of correct responses with the common feature primes is slightly higher than that without a prime, and the response times with primed common features are significantly shorter than without a prime. Priming with common features apparently made participants recognize emergent features quickly and easily. The common features are also, naturally, present in the vehicle. Thus, having a feature that is shared by both the topic and vehicle affects feature emergence in a very different manner than when the feature is only possessed by the vehicle. Given that the common features also come from the topic, variations in them are more limited than that of the vehicle features. In fact, Nueckles and Janetzko (1997) reported that different people agree on the same common features as interpretations of the metaphor. Furthermore, Becker (1997) showed that the common features are judged to be most important for metaphor interpretation. Therefore, priming with the common feature might give a well-constrained, general direction of the interpretation to the reader. As a result, it is likely that new features for a metaphor emerge through associations with common features. This is consistent with the findings that emergent features are relatively creative reactions to metaphors (Gineste et al., 2000), because the common features might be more active when the metaphor is primed than when the vehicle or topic term only is primed.

From these results, there are apparently interactions, both facilitative and inhibitory, among features in metaphor comprehension. Furthermore, because the feature derived from the vehicle had the greatest impact on emergent feature interpretation, it supports the interactive property attribution model. The property attribution model assumes that the literal level of abstraction is appropriate only for the topic term. The vehicle term is understood at a higher level of abstraction, specifically, a category. If the assumption is correct, then the primed features derived from the vehicle have a stronger affect on metaphor comprehension.

Previous research has shown that emergent features required more time to be recognized as interpretations of the metaphor than non-emergent features (Terai & Goldstone, 2011). Nueckles and Janetzko (1997) suggested the idea that metaphor comprehension proceeds in two stages. Based on these previous results and the findings in this experiment, we may speculate that metaphor comprehension proceeds in two processes. In the first process, a reader tries to interpret a metaphor based on the non-emergent features. If this does not produce a sufficiently high aptness evaluation, then the reader attempts to find emergent features, a longer and cognitively more taxing process. The first process could be ac-

completed according to the interactive property attribution model (Glucksberg et al., 1997). That is to say, at first, non-emergent features are discovered as interpretations through a process in which the vehicle is understood to be referring to a metaphoric category that includes the topic's literal referent as a member. Subsequently, new features become associated with non-emergent features.

This assumption has been incorporated into a simulation model but not validated by an experiment. The model (Terai & Nakagawa 2008, 2010) simulates feature emergence under the two-process assumption which consists of a categorization process followed by a dynamic interaction process. The categorization process is based on the interactive property attribution model and the dynamic interaction process represents interaction among features. The currently reported results support the two-process assumption. However the results did not provide unambiguous evidence for the two-process assumption. Therefore, more examination is required to verify it.

To elucidate the mechanism of feature emergence during metaphor interpretation, we used non-emergent features as primes. The experiment was conducted in order to explain feature emergence during the comprehension of metaphors taking the form of "TOPIC is VEHICLE." For this type of metaphor, the interaction could explain feature emergence. However, when "emergence" is explained in different types of metaphor comprehension (e.g. predicative metaphor comprehension), it might not be sufficient. Indurkha (2006) proposed an idea to explain how new representations emerge through a cognitive agent's interaction with the environment from the viewpoint of "interaction" and "Gestalt perception."

### Acknowledgments

We are deeply grateful to Dr. Angela H. Becker for allowing us to use their valuable data. This research is supported by MEXT's program "Promotion of Environmental Improvement for Independence of Young Researchers," KAKENHI Grant-in-Aid for Young Scientists (B) 23700160. We want to thank to Alex Nay for collecting data.

## Abstract

Metaphor comprehension involves the generation of novel semantic attributes, especially when a metaphor emphasizes a shared but atypical characteristic of the relevant concepts. The present functional magnetic resonance imaging (fMRI) study explores neural activation during the process of attribute generation known as feature emergence. The participants judged whether a presented semantic feature was an appropriate interpretation of a primed metaphor sentence. Two types of features were evaluated: emergent features that are not applicable to the respective concepts and only become salient in a metaphorical context and non-emergent features which are typical characteristics. In contrast to non-emergent features, processing of emergent features mainly involved prefrontal regions of the right hemisphere, including the precentral gyrus. The present results suggest that feature emergence necessitates a shift of semantic attention that drives a novel metaphor interpretation beyond the semantic elaboration implicated within the left prefrontal cortex.

**Keywords:** Metaphor comprehension; Feature Emergence; functional MRI.

## Introduction

It is widely accepted that the comprehension of metaphorical expressions entails greater semantic elaboration than for literal sentences, because the relevant concepts are not directly connected in terms of literal similarity, even though an expression is understandable (Ortony, 1979). Reflecting this salient nature of metaphors, it is also known that metaphor usage enhances recognition memory performance within reading tasks (Reynolds & Schwartz, 1983) and that it is more

persuasive when logical reasoning is less effective (Sopory & Dillard, 2002).

The primary form for metaphors consists of two concepts combined by the “*be*” verb, such as “*A is B*”, where (*A*) and (*B*) are known as the *topic* and the *vehicle*, respectively. This type of metaphor is believed to be interpreted through four types of features depending on whether the feature represents a typical characteristic of the concepts. In the first type of “common feature”, the topic and vehicle share a typical feature. For example, in the metaphor of “*ideas are fireworks*”, “*brilliant*” is a common feature, because both *ideas* and *fireworks* can be regarded as being brilliant. In the second type of “vehicle feature”, the feature is only typical of the vehicle concept. Taking the same metaphor example again, “*momentary*” would be a vehicle feature because it is only relevant to “*fireworks*”. In contrast to a vehicle feature, a topic feature is only a typical characteristic of the topic concept. “*Flash*” would be a topic feature in this example. Although these three feature types minimally involve a typical characteristic of either the topic or the vehicle concepts, the last type of “emergent feature” does not involve a typical characteristic of neither the topic nor the vehicle. However, non-emergent features only appear for interpretations of metaphorical context. The feature “*sudden*” is interpretable within the metaphor example, but it is not a typical characteristic of either the “*ideas*” topic or the “*fireworks*” vehicle. Gineste and colleagues (2000) claim that more than 60% of metaphoric interpretations involve emergent features, which suggests that

emergent features play a major role within metaphor comprehension.

Although previous cognitive neuroscience studies have explored the neural regions involved in metaphor comprehension, they have failed to distinguish between the interpretations of emergent and non-emergent features (e.g., Rapp et al. 2004; Shibata et al. 2007a, 2007b; Stringaris et al. 2007). Some studies indicate that literal and metaphorical sentence comprehension activates multiple cortical regions, including the ventro lateral prefrontal cortex near Brodmann areas (BA) 47 and 44/45, mainly in the left hemisphere (LH), and probably reflects normal semantic processing. In contrast, some other studies have reported fronto-temporal activation within the right hemisphere (RH) during the processing of verbally presented figurative expressions compared to literal expressions (e.g., Marshal et al. 2007; Stringaris et al. 2006). In particular, Marshal and colleagues (2007) found that the processing of word pairs forming novel metaphors, compared to conventional ones, elicited stronger activation within the posterior superior temporal sulcus and the right inferior frontal gyrus mainly in the RH, and Stringaris and colleagues (2006) found right-lateralized prefrontal activation when participants search for a wider range of semantic relationships between a metaphoric sentence and a word. However, others have reported the opposite pattern of lateralization (e.g., Rapp et al. 2004, Stringaris et al. 2007, Shibata et al. 2007b). Rapp and colleagues (2004) report that recognition of metaphors only elicits prominent brain activity in the LH—inferior frontal (BA45/47), inferior temporal (BA20) areas, and the posterior medial/inferior temporal (BA37) gyrus—with no RH activation.

The present study investigates the pattern of cortical involvement during metaphor comprehension. One possibility is, as Marshal and colleagues (2007) suggest, that the processing of novel metaphors involves the right hemisphere. Another possibility is that RH activation reflects some decision criteria processing of presented expressions. Shibata and colleagues (2007a, 2007b) suggest that right frontal regions are more activated when the metaphorical aspect is emphasized for judgments. Thus, they argue that metaphor comprehension requires association search over a wide range which involves RH activation.

The present study hypothesizes that feature emergence activates RH frontal regions during metaphor comprehension. In our previous studies, we have argued that feature emergence is enhanced with longer comprehension times, which suggests that feature emergence may involve interaction spreading out over the semantic network (Terai & Goldstone 2011). We apply the same paradigm within this fMRI study to explore the neural regions activated in feature emergence. We first develop a set of metaphors with features for which feature emergence occurs. In addition to non-emergent features, this set of metaphors was judged by participants while fMRI imaging was conducted.

## Materials and Method

### Participants

All participants ( $N = 10$ ; mean age = 23.3 years; range 21–29 years; 5 male, 5 female) were healthy, right-handed, native Japanese speakers. The current study was approved by the ethical committee of Tokyo Institute of Technology. All participants gave their informed consent before the experiment, and they were compensated for their participation (2000 JPY/hour).

### Materials

Ten metaphorical Japanese sentences of the style “*topic is vehicle*” (e.g., “Ideas are fireworks”) were created based on a behavioral experiment. The behavioral experiment used three feature types (emergent, non-emergent, and filler features). For each metaphor, an emergent (e.g., “sudden”), a non-emergent (e.g., “sparkle”) and a filler feature (e.g., “pray”) were created based on results of a behavioral study. One hundred and fifty five participants evaluated 16 metaphors and six features for each metaphor. The metaphors and participants were divided into four groups. Each participant evaluated the relationship between four metaphors and their features on a 7-point scale. They also evaluated the relationships between eight concepts (the topics and vehicles of the four metaphors) and the features of the metaphors, and rated the characteristics of metaphors (e.g., comprehensibility and novelty). Ten metaphors with higher mean ratings for comprehensibility (above 4) were selected as metaphors that can be easily interpreted. Each metaphor was then assigned with the three types of features, based on comprehensibility ratings of more than 5 (slightly comprehensible) from participants who could interpret a metaphor<sup>1</sup>. Features that fulfilled the following two criteria were classified as emergent features; 1) the mean adequacy rating was greater than three (neutral) and 2) the mean typicality rating was lower than that for the metaphor<sup>2</sup> [mean ratings ( $SD$ ) for metaphor, 5.01 (1.80), topic, 4.60 (2.10), and vehicle, 4.38 (1.99)]. In contrast, features with mean ratings for the metaphor of more than 3 and with higher mean ratings for the vehicle than for the metaphor were classified as non-emergent features [mean ratings ( $SD$ ) with the metaphor, 5.18 (1.81), topic, 4.85 (1.89), and vehicle, 5.88 (1.67)]. If the mean rating for a feature’s relationship with the metaphor was less than 3, the feature was classified as a filler feature [mean ratings ( $SD$ ) with metaphor, 1.80 (1.29), topic, 1.95 (1.43), vehicle, 2.05 (1.66)].

<sup>1</sup>The average proportion of participants who could interpret a metaphor was 33.0%.

<sup>2</sup>We expect that the relationships of an emergent feature with both the vehicle and with the topic are less than that with the metaphor. However, generally, metaphor interpretations can be regarded as a topic characteristic if it is not a typical characteristic. Participants tend to rate vehicles’ relationships with the metaphor highly. Thus, we consider the difference between the relationships with the vehicle and with the metaphor as being important.

## Procedures

fMRI scanning consisted of two sessions. For the first session (concept term condition), at the beginning of each trial, a fixation point “+” was presented for 900 msec on the computer screen. Then, participants were presented with a concept term, which was either a vehicle or a topic, for 3900 msec. They were asked to read the term covertly. Next, the fixation point “+” was presented for 900 msec again. Then, a feature (either an emergent, a non-emergent or a filler feature) was displayed on the screen for 4000 msec. The participants were instructed to respond concerning whether the feature is a typical characteristic of the concept (the vehicle or the topic) term during the presentation period. They held a response box in each hand and responded by pressing the right button (“Yes”) or the left button (“No”). The trials were pseudo-randomly ordered. Fixation trials were also intermixed pseudo-randomly.

In the second, metaphor session, the procedure was as follows: At the beginning of each trial, the participants were presented with a metaphorical sentence on the computer screen for 3900 msec. They were asked to silently read and interpret the metaphor. Then, the metaphor disappeared and a fixation point “+” was presented for 900 msec, followed by the presentation of a feature for 4000 msec. The participants were asked to respond “Yes” or “No” depending on whether the feature represented an adequate interpretation of the metaphor by pressing the right button (“Yes”) or the left button (“No”) during the presentation period. The trials were presented pseudo-randomly, such that the same metaphor never appeared in succession. Fixation trials were intermixed pseudo-randomly.

Participants were given instructions prior to performing the tasks. They were asked to think of nothing during presentation of the fixation point. We conducted a follow-up survey with a questionnaire. The participants were asked to evaluate the characteristics of the metaphors (comprehensibility, novelty, etc.) on 7-point scales.

## Imaging procedures

fMRI scans were conducted with the 3T GE SignaHDxt scanner (General Electric, Milwaukee, WI) at Tokyo Institute of Technology, Japan. High-resolution anatomical images were obtained using an FSPGR T1-weighted sequence [repetition time (TR) = 7.712 msec; echo time (TE) = 2.88 msec, flip angle (FA) = 11 deg, slice thickness = 1 mm; in-plane resolution =  $1 \times 1 \text{ mm}^2$ ]. Functional images were obtained using a GE-EPI sequence [TR = 2.0 sec, TE = 30 msec, FA = 90 deg, slice thickness = 3.0 mm, in-plane resolution =  $3.75 \times 3.75 \text{ mm}^2$ , slice gap = 1.0 mm].

## Imaging analysis procedures

Imaging analysis was performed using SPM8 (<http://fil.ion.ucl.ac.uk/spm/>). All the functional images were temporally aligned across the brain volumes, spatially registered to a MNI template, resampled

into 2-mm isotropic voxels, and then spatially smoothed with an 8-mm FWHM Gaussian kernel.

The present imaging analysis focused on the metaphor condition. For each participant, a voxel-wise GLM analysis was first performed to estimate parameter values for the MR signal magnitudes. The trial period for the metaphor condition was modeled by two independent regressors, one coding metaphor-sentence presentation, and the other coding feature-word presentation that involved a feature judgment, convolved with a canonical HRF (together with time and dispersion derivatives). The metaphor regressor lasted from presentation onset to offset of the sentence, while the judgment regressor lasted for 1000 msec, which was determined based on the mean RTs for each condition for each participant. The estimated parameters during feature judgment were then contrasted between the emergent and non-emergent conditions.

Parameter estimates for each participant were submitted to a group analysis using a voxel-wise random-effect model. Whole-brain exploratory analysis was performed to identify the brain regions showing activity during feature judgment in the emergent condition relative to the non-emergent condition. Due to the small size of the sample in the present study, significance was assessed by a relatively liberal threshold of ten or more continuous voxels above  $p < .001$  ( $Z = 3.3$ ) uncorrected.

## Results

### Behavioral results

The mean reaction times in the concept term condition are shown in Figure 1. A two-way ANOVA with reaction times for the feature conditions and concept types as factors showed a significant main effect for feature types [ $F(2, 18) = 46.35$ ,  $p < .01$ ]. A post-hoc t-test showed that reaction times for the emergent features were longer than reaction times for non-emergent features [ $t(9) = 4.99$ ,  $p < .01$ ]. These results suggest that emergent features are more involved in evaluation-related processes, which is consistent with previous studies (Gineste et al. 2000).

Figure 1: Mean reaction times ( $\pm SEs$ ) for emergent, non-emergent and filler features (in concept term condition)

Figure 2: Mean reaction times ( $\pm SE$ s) for emergent, non-emergent and filler features (in the metaphor condition)

Figure 2 shows the mean reaction times for the metaphor condition. A one-way ANOVA for reaction times in the feature condition revealed that significant main effect of feature type [ $F(2,18) = 29.20, p < .01$ ]. The reaction times for the emergent and the non-emergent features were significantly longer than those for the filler features at the 1% level. However, there was no significant difference between reaction times for emergent features and for non-emergent features ( $p=.19$ ). These results indicate that emergent features are activated within metaphor processing as much as non-emergent features.

The average proportions of “Yes” responses are shown in Table 1. All participants responded “No” for almost all the filler features. The proportions of “Yes” responses for emergent features in the metaphor condition (51.0%) were significantly lower than for the non-emergent features (67.0%) [ $F(1,9) = 12.5, p < .01$ ]. In the concept term condition, when the target was the vehicle, the average proportion for non-emergent features (85.0%) was higher than that for emergent features (34.0%) [ $F(1,9) = 157.1, p < .01$ ]. When the target was the topic, the average proportion for emergent features was 45.0%, while for non-emergent features, it was 30.0% [ $F(1,9) = 5.55, p < .05$ ]. Collectively, these findings suggest that emergent features were not easily understood compared to non-emergent features, which is consistent with previous studies (Terai, Goldstone 2011).

These behavioral results suggest that there are distinct differences between the processing of emergent and non-emergent features. In particular, the results indicate that non-emergent features are recognized as a typical characteristic of the vehicle but emergent features are not.

Post-scan evaluations of the metaphor characteristics revealed that the mean rating of the metaphors’ comprehensibility was 4.00 on the 7-point scale (1: incomprehensible - 7: comprehensible), suggesting that the participants understood the presented metaphors. The mean rating for the metaphors’ novelty was 4.29, suggesting that the participants did not re-

Table 1: Mean proportions for emergent and non-emergent (%). For almost all of the filler features, the proportions were almost 0%.

	Concept Term Condition		Metaphor Condition
	Vehicle	Topic	Metaphor
Emergent	34.0	45.0	51.0
Non-emergent	85.0	30.0	67.1

gard the metaphors as being very conventional.

### Imaging results

In order to investigate the difference between the processing of emergent and non-emergent features within metaphor comprehension, we analyzed the differential contrast between the activation of emergent features and for non-emergent features in the metaphor condition (Figure 3 and Table 2). The emergent feature condition showed significant activation in the precentral gyrus (BA6) in the RH and the cingulate gyrus. In contrast, in the concept term condition, no activation was observed in the emergent condition compared to the non-emergent condition.

### Discussion

The present study has explored the pattern of neural activation during feature emergence within metaphor comprehension. Emergent features elicited higher levels of activations in the right precentral gyrus (BA6) and the cingulate gyrus in contrast to non-emergent features in the metaphor condition.

Higher levels of activation have been observed in the right precentral gyrus and the cingulate gyrus during the reading of anomalous metaphors compared to literal sentences and in the right precentral gyrus compared to conventional metaphors (Ahrens et al. 2007). The metaphors were presented as a sentence (e.g. “The theory framework of this theory is very loose”) and the participants were asked to read the sentence and press a button when they finished. In such a situation, participants may search for the relationships between the topic (e.g. “the theory framework”) and the feature (e.g. “loose”) presented in the sentence. In particular, in the anomalous metaphor sentence condition (e.g. “Their capital has rhythm”), they may search for a wider range of associations between the topic (e.g. “their capital”) and the feature (e.g. “have rhythm”). One may speculate that the precentral gyrus is more activated when participants search for a relationship between a metaphor and a novel feature. Accordingly, emergent features may require additional cognitive processing in searching for a wider range of semantic relationships for the metaphor.

Furthermore, these right frontal regions have been associated with stimulus-driven attentional reorientation (Corbetta & Shulman 2002). It is thus feasible to assume that the presentation of emergent features shifts the participants’ seman-

Table 2: Activation contrasts obtained for emergent features versus non-emergent features in the metaphor condition. (Activations listed here were obtained at a voxel level of two-tailed  $p < .001$ , uncorrected, clusters of 10 or more)

Z value	Cluster size	MNI(x)	MNI(y)	MNI(z)	BA	Side	Cerebral Region
4.40	10	52	-2	52	6	R	precentral gyrus
4.10	54	-2	-24	24	24	L/R	cingulate gyrus

Figure 3: Activation patterns for the differential contrasts between emergent features versus non-emergent features in the metaphor condition (two-tailed  $p < .001$ , uncorrected, clusters of 10 or more)

tic attention to words that are triggered by the presentation of an emergent feature. In other words, these results suggest that the presentation of an emergent feature prompts participants to modify their comprehension processes to incorporate interaction between the topic and the vehicle. That would be consistent with experimental results (Gineste et al. 2000) which indicate that the processing of emergent features is facilitated by interaction between the target and the vehicle concepts.

Previous studies have suggested that searching for a wider range of semantic relationships within metaphor comprehension elicits activation of the right inferior frontal gyrus (Stringaris et al. 2006, Shibata et al. 2007a). However, the results from the present study failed to demonstrate that searching for a wider range of semantic relationships led to activation of this area. In Stringaris et al. (2006), the word was presented with the metaphor and the participants judged the relationship. In contrast, in the present study, the feature was presented after the metaphor had disappeared and we have analyzed data obtained during the interval between feature presentation onset and the participants' responses. Thus, the results from the present experiment only reflect the recognition processing of the feature. The present study's result observed no significant activation differences for the right inferior frontal gyrus.

Moreover, in the present study, emergent features were not spontaneously generated within the interpretative processing of the metaphors. Accordingly, the results only represent a part of the mechanisms of feature emergence within metaphor comprehension. It should also be noted that only ten individ-

uals participated in the present study which only consisted of ten stimulus item for each condition. In order to obtain more robust results, further experiments are needed with more participants and more items.

Nonetheless, the present results indicate that the right frontal area is involved in the processing of emergent features. Accordingly, it is not possible to account for the involvement of the RH merely in terms of metaphor novelty (Marshall et al. 2007, Ahrens et al. 2007), for it may rather reflect feature emergence. If RH involvement can explain differences between the cognitive processing of figurative and literal sentences, feature emergence may be related to metaphor recognition when reading sentences.

## Acknowledgments

We are deeply grateful to Dr. Noburu Hidano, Dr. Hiroyuki Akama and Dr. Atsushi Terao for helping our research. This research is supported by MEXT's program "Promotion of Environmental Improvement for Independence of Young Researchers", KAKENHI Grant-in-Aid for Young Scientists (B) 23700160.

## Abstract

Reconstructing explanations is crucial for the progress of science. We focused on the transition of interest in a key fact that contradicts the preceding explanation and has a central role in its reconstruction. We used a short story as an experimental material in which the participants first constructed a naïve explanation and reconstructed it. First, when the naïve explanation was rejected, a new explanation was required, after interest in the key fact was inhibited. Second, hypothesized premises not inconsistent with the naïve explanation were sought to protect the naïve explanation. Third, interest in the key fact was recovered through the process of the explanation reconstruction. Last, we facilitated the explanation reconstruction by having the participants focus on the key fact.

**Keywords:** eye movement analysis; scientific explanation; key fact; insight; naïve concept.

## Introduction

Scientific activities aim to understand the world by two ways: descriptive and explanative (Simon, 2000). Descriptive understanding grasps the nature and characteristics of phenomena by observations and experiments; explanative understanding grasp the mechanisms behind the phenomena and the reasons why such phenomena appear.

Through the history of science, descriptive understanding is usually established first and then explanative understanding is investigated. For example, Kepler's law described the orbit of the planets, and then Newton's law explained why they moved in such orbits. Science has developed while pursuing such explanative understanding about phenomena. The construction of explanations is crucial for science.

As historical facts, we can confirm many cases where the explanation for a certain phenomenon was completely changed because the structures of the explanation and the concepts of objects were essentially shifted. Such cases are generally observed in the history of science: e.g., the shift from the caloric theory to the oxygen theory and the transition from Newton's traditional theory to Einstein's relative theory.

As an example, consider the change of the caloric theory to the oxygen theory. Initially, in the caloric theory, burning was explained as the release of caloric. After an inconsistency was observed about the caloric theory, the weight increase after burning, a new explanation was required. In the current study, we call such an instance that contradicts a preceding explanation and must be interpreted by a new explanation a "key fact." The change of the explanation from the caloric theory, i.e., burning released caloric, to the oxygen theory, i.e., burning is connected with oxygen, was es-

tablished by reinterpreting the key fact, i.e., the increase of weight by burning.

Note that there are two ways of understanding a key fact. One is by local modification and slight expansion of a previous explanation. The other is understanding by an essential change of a previous explanation. An interpretation about key facts completely changes between the two types of understanding: a completely different interpretation about a key fact is given in each of the two theories. In the oxygen theory, the key fact is explained by the connection with oxygen, but in the caloric theory, it is explained by the release of phlogiston that has negative weight.

Difficulties exist in such essential reconstruction of explanations. Interesting processes are often observed that prevent such reconstruction. One is the stubborn refusal to abandon explanations. People prefer to protect an established explanation by modifying and adding new reservations than shifting to a new one. In such a case, to protect the old explanation, people may focus on other irrelevant facts and arbitrarily proposed premises that are not inconsistent with the previous explanation. They sometimes add secondary explanations as protection. For example, in the caloric theory, a premise, phlogiston might have negative weight, was hypothesized and investigated.

Now we summarize the problems we address in this paper. We investigate a situation in which fact F that cannot be interpreted by explanation A is observed, and new explanation B is required. For the transition from explanation A to B, a mental leap is needed, meaning that fact F must be reinterpreted. We call fact F a key fact and investigate how it is processed through a reconstruction of the explanation.

The research questions and hypotheses are drawn in the following. We hypothesize that reinterpretation of key facts is crucial for the transition to a new explanation. However, people tend to pursue unrelated facts or arbitrarily hypothesized premises to protect old explanations, and such reinterpretation of key facts may be postponed. As a result, the interest in key facts is inhibited, and the reconstruction of explanation is impeded.

We propose two hypotheses:

**Hypothesis 1** When a previous explanation is rejected and a new explanation is required, interest in a key fact may be temporarily inhibited.

**Hypothesis 2** With the inhibition of interest in a key fact, other facts and hypothesized premises that are not inconsistent with a previous explanation are searched for, and

Introduction	Taro was driving to Las Vegas by rental car. His car broke down in a small town. He decided to get a haircut while the car was repaired. There are only two barbershops in the town: Alf's shop and Bally's shop. He is considering which to select.
Filler (Place)	Alf's shop is on the ground floor of a building located in the east area of town. In the building, there is a stationary shop. Bally's shop is along a street running in the west area of town. There is a supermarket near it.
Key Fact	Alf's hair is unkept, and the nape of his neck is messy. Bally's hair is beautifully cut, and the nape of his neck is neat.
Filler (Barbershop)	The windows of Alf's shop are light blue, and natural scene are pictured on the cover pages of the books in the shop. The windows of Bally's shop are light green, and various letters are written on the cover pages of the books in the shop.
Filler (Time)	Alf's shop is open until late. He often eats dinner at his favorite restaurant near the shop. Bally's shop is open early. He usually walks around the shop in the morning.

Figure 1: Barber task (used in Experiment 1).

the old explanation is protected.

We are also interested in the transition process from a former to a new explanation. We confirm that the reinterpretation of a key fact has a central role in the transition of the explanation. Two additional hypotheses are drawn.

**Hypothesis 3** The recovery of interest in a key fact is observed through the process of the explanation reconstruction.

**Hypothesis 4** We may promote explanation reconstruction by having participants focus on a key fact.

### Concern for a key fact

We used a short story as an experimental material because people understand a text by unifying meanings while adding implicit information and inferences about omitted and un-presented sentences (Rumelhart & Ortony, 1977; Seifert & Robertson, 1985).

We used a text that was modified from a barber task (Gardner, 1978). Figure 1 shows the material. In this material, (1) a naïve explanation is initially constructed by a key fact; (2) a new explanation is required where a shift of perspective is needed; (3) a rational explanation is constructed by reinterpreting the key fact.

In the story, in a town with only two barbershops, a character is looking for a barber and must to select either barber A whose staff has unkept hair or barber B whose staff's hair is beautifully cut. Initially, participants may select barber B where the following naïve explanation is given: "a barber with beautiful hair is very skilled." However, a new explanation is required after being informed that the character selected barber A. The fact, "barber A's hair is messy and barber B's hair is neat," contradicts the initial explanation. Therefore, in the story, the key fact that must be reinterpreted is:

"barber A's staff has unkept hair and barber B's staff has neat hair." The reconstructed explanation from Gardner (1978) is: "each does the other's hair because there are only two shops in town; therefore, barber A's staff who did barber B's staff's hair is more skilled." In the reconstructed explanation, the key fact becomes evidence for selecting barber A but in the naïve explanation, it is evidence for selecting barber B. The meaning of the key fact has completely shifted with the transition from the initial to the reconstructed explanation.

In the text, other unrelated facts than the key fact are described; therefore, other secondary additional explanations may be possible to protect the initial naïve explanation. However, if participants construct such an explanation based on other facts than the key facts, the contradiction remains unsolved: the character selects a messy barber. The shift to the reconstructed explanation by reinterpreting the key fact is required for consistently understanding the story structure.

## Experiment 1

We confirmed the validity of the barber's story as an experimental task to examine our hypotheses. Experiment 1 confirmed whether most participants initially constructed the naïve explanation. Additionally, to confirm Hypothesis 2 preliminary, participants reconstructed their explanations after the naïve explanation was rejected.

The definitions of the naïve and reconstructed explanations are described below.

**Naïve explanation** A barber who has beautiful hair is very skilled.

**Reconstructed explanation** Each does the other's hair because there are only two shops in the town; therefore, barber A's staff who did barber B's staff's neat hair is more skilled.

## Subjects

Fifty-three undergraduate students participated in Experiment 1.

## Task

Figure 1 shows the barber task used in Experiment 1.

## Procedure

Experiment 1 was constructed of two phases: the initial explanation phase and the reconstruction phase. In the initial explanation phase, the participants read the story while thinking about which barbershop to select and their task was to construct an explanation for their decision. The initial explanation phase was followed by the reconstruction phase in which the naïve explanation was rejected, and they were required to reconstruct their explanation of the story.

## Results

Forty four of the 53 participants initially constructed the naïve explanation. A binomial test revealed that they primarily constructed naïve explanations (two-sided:  $p < .01$ ). Moreover, the reconstructed explanations by the 44 participants were classified into four types (Table 1). Three other explanations than the reconstructed explanation were based on such facts about place as “shop B is located near the repair shop,” and about time such as “shop B is open until late,” and hypothetical information not included in the story. A chi-square test revealed a significant difference in the numbers of these explanations ( $\chi^2(3) = 10.8, p < .05$ ), and a multiple comparison using Ryan’s method showed that the explanations based on place and time were constructed significantly more than the reconstructed explanation ( $p < .01, p < .01$ ).

Table 1: Produced second explanations.

Explanation	#	Example of description
Target (reconstructed explanation)	3	Each does the other's hair because there are only two shops in the town; therefore, Bally's staff who did barber Alf's beautiful staff's hair is more skilled.
Place	15	Alf's shop was near the car repair shop.
Time	18	Taro wanted to get a haircut late in the evening.
Misc	11	-

Some descriptions were classified into multiple categories because they included multiple facts.

These results confirmed the validity of the barber task as an experimental task for our study. Additionally, we confirmed that the participants tended to add secondary explanations based on the facts about place and time to protect the naïve explanation, preliminarily supporting Hypothesis 2.

## Experiment 2

We confirmed both the inhibition of interest in the key fact (Hypothesis 1) and resumption of interest (Hypothesis 3) us-

ing eye movement analysis to capture the transition of interest.

## Subjects

Twenty-one undergraduate students participated in the experiment.

## Task

The story was displayed on a computer screen. The filler (barbershop) part of the text (Figure 1) was removed due to limitations of the display size.

## Procedure

The experiment was conducted individually, and participant eye movements were recorded using a Tobii T60 eye tracker.

As in Experiment 1, in the initial explanation phase, the participants were required to explain the story. Their fixation ratios of the key fact during the initial explanation phase were used as the baseline for analysis of the subsequent reconstruction phase. The fixation ratio of each fact was normalized by the number of letters that were included in each part.

After the initial explanation phase, the participants were reconstructed their explanations as answers to a quiz. When the participants found an idea, they reported it. They did the experiment at their own pace. When they gave another explanation than the reconstructed explanation as the target, they were told that it was not correct and were told to reconsider. This phase was continued for 30 minutes; when each participant constructed the reconstructed explanation, it was terminated.

## Results

**Inhibition of fixation on key fact** To examine the inhibition of interest in the key fact after the naïve explanation was rejected, we analyzed the fixation ratio of the key fact part in the initial stage of the reconstruction phase. First, we examined whether the fixation ratio of the key fact was less than the baseline obtained in the initial explanation phase and the other facts (place and time).

Figure 2 shows the fixation ratio of each of the facts (place, key, and time) during the first minute and the subsequent minute in the reconstruction phase.

In the first minute (0–60 sec), a t-test indicated no significant differences between the fixation ratio of the key fact and the baseline ( $t(20) = 1.62, n.s.$ ). A one-way ANOVA showed a significant main effect of the three facts (place, key, and time) ( $F(2, 40) = 8.97, p < .001$ ), and a multiple comparison using Ryan’s method showed that the fixation ratio of the fact about place was significantly higher than those of the key fact and the fact about time ( $p < .05, p < .05$ ).

Next, we conducted the same analysis on the subsequent minute (60–120 sec). A t-test indicated a significant difference between the fixation ratio of the key fact and the baseline ( $t(20) = 2.86, p < .01$ ). A one-way ANOVA showed a significant main effect of the three facts (place, key, and time) ( $F(2, 40) = 4.36, p < .05$ ), and a multiple comparison

using Ryan's method showed that the fixation ratio of the key fact was significantly lower than the place and time facts ( $p < .05$ ,  $p < .05$ ).

In the subsequent minute, we confirmed that the fixation ratio of the key fact was significantly lower than the baseline and the place and time facts. These results support that interest in the key fact was inhibited when the naïve explanation was rejected.

On the other hand, in the first minute, our prediction was not observed; the fixation ratio of the fact about place was substantially higher. This result might be affected by the order of the three facts, which were arranged as place, key, and time (see Figure 1). The participants probably read the story in this order, reflecting the result in the first minute.

The overall results of Experiment 2 supported Hypothesis 1.

Figure 2: Transition of fixation ratio of each fact.

**Resumption of fixation on key fact** Next, we analyzed the process of recovering interest in the key fact to build reconstructed explanation (Hypothesis 3). We focused on the 11 of 21 participants who successfully constructed the reconstructed explanation and analyzed the transition process of their fixation ratio of the key fact part.

Figure 3 shows the transition with the progress of three phases: the first 60 seconds, the last 60 seconds before reaching the reconstructed explanation, and the residual between them.

A one-way ANOVA showed a significant main effect of the three phases ( $F(2, 20) = 7.62$ ,  $p < .005$ ), and a multiple comparison using Ryan's method showed that the fixation ratio of the key fact in the last phase was significantly higher than those in the first and middle phases ( $p < .05$ ,  $p < .05$ ). The interest in the key fact gradually improved even though the ratio in the middle phase was not greater than in the first phase, partially supporting Hypothesis 3.

### Experiment 3

In Experiment 2, we observed the inhibition of interest in the key fact after the naïve explanation was rejected (Hypothesis 1).

Figure 3: Transition of fixation ratio of key fact in successful group.

This means that the participants searched for unimportant facts that did not contradict the naïve explanation.

In Experiment 3, we examined whether forced recovery of interest in the key fact could facilitate the reconstruction of their explanations (Hypothesis 4) by externally controlling interest in the key fact.

### Subjects

Forty-one undergraduate students participated in this experiment.

### Procedure

This experiment was conducted in small groups on personal computers for the stimulus presentation and data acquisition.

The participants were divided into two experimental conditions: highlighted (21 participants) and non-highlighted (20 participants). In the highlighted condition, the key fact was colored red to facilitate interest in it; the participants were instructed that the highlighted sentences were crucial for finding the right explanation. There was no such highlight in the non-highlighted condition.

In the initial explanation phase, the participants constructed explanations about the story as in Experiments 1 and 2. Then, in the reconstruction phase, they were also required to reconstruct their explanations and report them by computer keyboard. After reporting their explanations, they received a message: "since there is another reasonable explanation acceptable to all, please reconsider." They were told that there was an evaluator in another room connected by the Internet, even though no such evaluator existed, and the same message was always returned. The maximum time of the reconstruction phase was 15 minutes, and the data were analyzed until they reached reconstructed explanations.

### Results

The explanations that were constructed in the initial explanation phase were mostly naïve explanations (19 of 21 in the

highlighted condition and 18 of 20 in the non-highlighted condition).

Next, we analyzed the facts to which the participants referred until they reached the reconstructed explanation in the reconstruction phase. The referenced facts were identified by their description about the explanations. The ratio of each of the referenced facts in the generated explanations is shown in Figure 4.

A two-way ANOVA was conducted with the experimental conditions (highlighted and non-highlighted) as a between-participant factor and the facts (place, key, and time) as a within-participant factor. There was neither a significant main effect of the experimental conditions nor of the facts ( $F(1, 33) = .16, n.s.$ ;  $F(2, 66) = 1.15, n.s.$ ), but there was significant interaction between the conditions and the facts ( $F(2, 66) = 8.55, p < .001$ ). A multiple comparison using Ryan's method showed differences between the highlighted and non-highlighted conditions of the key and place facts ( $p < .05, p < .05$ ). There were also significant differences between the key and place facts in the highlighted condition ( $p < .05$ ), and the key fact and the place and time facts in the non-highlighted condition ( $p < .05, p < .05$ ).

These results suggest that the participants in the highlighted condition attempted to reinterpret the key fact. On the other hand, in the non-highlighted condition, there was little mention of the key fact. When there was no facilitation of interest in the key fact, the participants tended to modify their explanation based on other facts, supporting Hypothesis 2 that was preliminary supported in Experiment 1.

Figure 4: Ratio of referenced facts for generating explanation.

Finally, the ratios of the accumulated number of the participants who reached the reconstructed explanation in the reconstruction phase are shown in Figure 5. A chi-square test showed significant differences between the two experimental conditions at 10 and 15 minutes ( $\chi^2(1) = 6.26, p < .05$ ;  $\chi^2(1) = 7.79, p < .01$ ).

These results indicate that enhancing interest in the key fact facilitated the reconstruction of the naïve explanation, and

shifting to the reconstructed explanation supporting Hypothesis 4.

Figure 5: Ratio of accumulated number of participants who generated consistent explanations.

## Discussions and Conclusions

In our study, we focused on reinterpretation of a key fact for explanation reconstructions and examined the inhibition of interest in it and the improvement of interest in it by eye-movement analysis. The following is a summary of our experiment.

- When the naïve explanation was rejected by contradictions with the key fact and a new explanation was required, interest in the key fact was inhibited (Hypothesis 1 was supported).
- In such a situation, other facts and hypothesized premises not inconsistent with the naïve explanation were searched for and focused on, and the naïve explanation was protected (Hypothesis 2 was supported).
- Interest in the key fact was recovered through the process of the explanation reconstruction, especially before reaching the solution (Hypothesis 3 was partially supported).
- We facilitated the explanation reconstruction by having the participants focus on the key fact (Hypothesis 4 was supported).

In studies of hypothesis generation and testing, some human biases have been confirmed. For example, confirmation bias gathers positive instances to confirm hypotheses (Wason, 1960), and established hypotheses are maintained against anomalous data (Chinn & Brewer, 1998; Mason, 2001).

In the educational psychology domain, it has also been confirmed that naïve concepts that are not supported by related evidences are held strongly (McCloskey, Washburn, & Felch, 1983; Watts & Zylberstan, 1981). Watts and Zylberstan (1981) studied junior high-school students' naïve concepts about the inertia law and concluded that even if they received accurate knowledge about the law from lectures, they repeated the naïve explanation for events related to it.

In our experiments, we set up an experimental situation in which the participants reconstructed the naïve explanation. Theories in scientific activities were established based on the accumulated results of experiments through history in which the fixation to an explanation may be much stronger. Note that similar phenomena were observed using a short story in the laboratory setting of our current study.

The situation requiring a shift in explanations in our experiments seems similar to the settings dealt with in studies of insight problem solving. Here, mental constraints arising from the perceptual features of a problem and past experiences create an impasse and prevent problem solvers from finding the new relations required to solve the problem. These mental constraints are gradually relaxed unconsciously in some cases even if problem solvers meet an impasse, where they often ignore key evidence that leads to a solution. With activities that do not follow these mental constraints and acceptance of such crucial instances for solutions, problem solvers gradually reach a solution (Knoblich, Ohlsson, Haider, & Rhenius, 1999; Knoblich, Ohlsson, & Raney, 2001; Ohlsson, 1992; Terai & Miwa, 2003). In our experiment, we also observed such a recovery process that of focused on key facts.

It is difficult to manage interest in facts without the influence of hypotheses and concepts that were previously constructed (Kaplan & Simon, 1990; Luchins & Luchins, 1950; Wason, 1960). For example, Bilalic, McLeod, and Gobet (2008) used a rule discovery task that required participants to search for a better solution than the one they had already found. Their study indicated that the participants were unconsciously prevented from searching for facts that were unrelated to the existing solution, even if they were instructed to seek alternatives. This result also indicates that human behavior is largely constrained by constructed hypotheses and concepts.

In Experiment 3 of our study, even though we controlled the participant interest in the key fact that contradicted the naïve explanation by highlighting it, there was no significant difference between the highlighted and non-highlighted conditions during the first five minutes. Moreover, only half of the participants constructed the reconstructed explanation, even if such external stimuli were given. This suggests that the inhibition of interest in the key fact that contradicted the naïve explanation remained even after deep consideration for 15 minutes. We must study the interaction between conscious and unconscious activities by combining verbal protocols and eye movement analysis to understand the process of shifting explanations in more detail.

## Abstract

It is crucial for computers to detect metonymic expressions because sentences including them may have different meanings from literal ones. In previous studies, detecting metonymies has been done mainly by rule-based and statistical approaches. The problem of current metonymy detection is that using syntactic and semantic information may be not enough to detect metonymic expressions. In this study, we propose an approach for detecting them with associative information between words. We evaluated our method by comparing it with a baseline that uses syntactic and semantic information. As a result, our method showed significantly better accuracy (0.84) of judging words as metonymic or literal expressions than that of the baseline.

**Keywords:** Metonymy; Association Experiment; Associative Concept Dictionaries; Verbs; Nouns

## Introduction

Metonymy is a figure of speech, where one item's name represents another which usually has a close relation with the first one. The metonymic relation, as shown in Table 1 (Lakoff & Johnson, 1980; Taniguchi, 2003; Yamanashi, 1988), has different patterns which are classified predominately into two types: spatial contiguity and temporal contiguity (Taniguchi, 2003). Below is a Japanese example for 'Container for Content':

*kare-ga isshoubin-wo nomihoshita*  
(He drank up a 1.8-liter bottle.)

The Japanese sentence above means literally that he drank up the bottle. Of course, it does not mean that he drank or ate the bottle itself, but its content, usually Japanese sake. Japanese sake is generally in a large bottle made from glass, and called *bin* in Japanese. It has a capacity of 1.8 liters, *isshou*. Therefore, the above example sentence where *isshoubin* is a metonymic expression means that he drank up Japanese sake in a 1.8-liter bottle. Since a sentence including metonymy is grammatically correct on a literal level, it is difficult for computers to grasp its true meaning as humans do.

Table 1: Metonymic expressions with spatial contiguity and temporal contiguity.

Metonymic patterns	Examples of sentences (metonymic reading)
-spatial contiguity-	
Container for Content	<i>kare-ha glass-wo nonda</i> 'He drank the glass (liquid).'
Producer for Product	<i>kare-ha Mahler-wo kiita</i> 'He listened to Mahler (symphony).'
Controller for Controlled	<i>Nixon-ga Hanoi-wo bakugekishita</i> 'Nixon (government) bombed Hanoi.'
Object Used for User	<i>gakuseifuku-ga aruiteiru</i> 'The school uniform (student) is walking.'
Material for Product	<i>kare-ha caffeine-wo nonda</i> 'He drank caffeine (soft drink).'
Others	<i>riiron-ga sore-wo jishshoushita</i> 'The theory (proposer) claimed that.'
Metonymic patterns	Examples of sentences (metonymic reading)
-temporal contiguity-	
Result for Cause	<i>kanojo-ga sekimensuru</i> 'She is blushing.' (She is ashamed)
Cause for Result	<i>kare-ga sakazuki-wo katamukeru</i> 'He is tipping the sake cup.' (He is drinking the Japanese sake)

In English metonymy detection, most previous studies have taken mainly rule-based and statistical approaches. The rule-based approach uses semantic networks and hand-crafted rules to detect metonymies (Bouaud, Bachimont, & Zweigenbaum, 1996; Fass, 1991; Iverson & Helmreich, 1992). The representative work of statistical approach used corpus-based metonymy resolution on location names (Markert & Nissim, 2003). Moreover, by using syntactic, semantic, encyclopedic, or collocation information as machine learning features, some conventional studies for detecting metonymic expressions were suggested (Markert & Nissim, 2007; Nastase & Stube, 2009). Their methods are effective, but they only dealt with metonymies on country names and companies. When considering the variety of metonymic patterns in Table 1, it is desirable to be able to detect various

Table 2: Semantic relations used in experiments.

Semantic relation	Content
Agent	Subject of an action
Object	Object of an action
Source	Source of an action
Goal	Goal or end of an action
Duration	Time or term of an action
Location	Location or space during an action
Tool	Tool or material of an action
Aspect	Aspect, degree or frequency of an action
Reason	Reason or cause of an action
Purpose	Purpose of an action

metonymies. In Japanese, although with small data sets, the manually constructed case frame dictionary and Goi-Taikai—A Japanese Lexicon (Ikehara et al., 1999), which consist of syntactic and semantic information, have been used for detecting various metonymies (Murata, Yamamoto, Kurohashi, Isahara, & Nagao, 2000; Suga & Ishizaki, 2006).

The problem of current metonymy detection is that using syntactic and semantic information may not be enough to detect metonymic expressions because in our daily conversations and readings we understand metonymic expressions in sentences by using associative relations between words unconsciously. As Yamanashi described (Yamanashi, 1987, 1988), metonymic relations relate to psychological association; we consider that computers also need associative information to improve the accuracy of metonymy detection.

By using our associative concept dictionaries for verbs and nouns (hereinafter referred to as Verb-ACD and Noun-ACD, respectively) (Okamoto & Ishizaki, 2001; Teraoka, Okamoto, & Ishizaki, 2010), our previous study proposed an approach to metonymy detection with associative information and showed its effectiveness (Teraoka, Okamoto, & Ishizaki, 2011). In this study, we focus on detecting only metonymic expressions of the spatial contiguity type as our first step, and enhance our approach by using decision tree learning.

### ACD Construction

In this section, we describe the Verb-ACD and the Noun-ACD that we use to extract associative information for detecting metonymic expressions.

#### Verb-ACD

The Verb-ACD (Teraoka et al., 2010) consists of the following three elements: stimulus words, associated words from the stimulus words with semantic relations, and word distances among them. The stimulus words are basic verbs with semantic relations that corresponded to deep cases. We quantify word distance between the stimulus word and the associated one.

**Association Experiments** To collect associative information on verbs, we conducted large-scale association experiments on the web. The stimulus words were verbs from Japanese elementary school textbooks, and we prioritized 200 of them that were entry words in a basic Japanese dictionary

(Morita, 1989). We prepared ten semantic relations shown in Table 2: Agent, Object, Source, Goal, Duration, Location, Tool, Aspect, Reason, and Purpose. The experiment participants were requested to give associated words of the stimulus words with these semantic relations.

**Quantification of Word Distances** We used the linear programming method to calculate distances between stimulus words and associated ones. As shown in Eq. (1), the distance  $D(x, y)$  between the stimulus word  $x$  and the associated word  $y$  is expressed with the following formulae:

$$D(x, y) = \frac{7}{10}IF(x, y) + \frac{1}{3}S(x, y) \quad (1)$$

$$\text{where } IF(x, y) = \frac{N}{n(x, y) + \delta}, \quad (2)$$

$$\delta = \frac{N}{10} - 1 (N \geq 10), \quad (3)$$

$$S(x, y) = \frac{1}{n(x, y)} \sum_{i=1}^{n(x, y)} s_i(x, y). \quad (4)$$

The distance consists of the inverse of frequency of an associated word  $IF(x, y)$  in Eq. (2) and the average of the associated word order  $S(x, y)$  in Eq. (4). Each coefficient was obtained by using the Simplex Method. Let  $N$  denote the number of participants in the experiments, and  $n(x, y)$  denote the number of participants who responded with the associated word  $y$  to the stimulus word  $x$ . Let  $\delta$  in Eq. (3) denote a factor which limits  $IF(x, y)$  to a certain numerical level when  $N$  increases. Let  $s(x, y)$  denote the associated word's order of each participant.

Each semantic relation of two words is expressed by each distance where the smaller the distance is, the closer two words are. For example, when a stimulus verb is the Japanese word, *aruku* 'walk' and the semantic relation is Source, one of the associated words is *ie* 'home' of which the distance is 1.38. Meanwhile, the distance between walk and *kaisha* 'office' is 9.92. The relation of these distances thus expresses a degree of association from the verb with the semantic relation.

Currently, there are 345 stimulus verbs in the Verb-ACD and the number of all participants is approximately 1,300. The participants were undergraduates and graduate students of Keio University. Each stimulus verb was presented to 40 participants. There were approximately 135,000 associated words. When all overlapping words were eliminated, there were 30,000 associated words.

#### Noun-ACD

The Noun-ACD consists also of stimulus words, i.e., nouns, associated words with semantic relations, and word distances among these words (Okamoto & Ishizaki, 2001). Table 3 shows the semantic relations and examples when the stimulus word is a Japanese word *jisho* 'dictionary'. Currently, the number of the stimulus words in the Noun-ACD is 1,100 and

Table 3: Examples of associated words in the Noun-ACD when the stimulus word is ‘dictionary’.

Semantic relation	Examples of associated words
Hypernym	<i>shuppanbutsu</i> ‘Publication’, <i>hon</i> ‘Book’
Hyponym	<i>waeijisho</i> ‘Japanese-English dictionary’
Part / Material	<i>midashigo</i> ‘Entry word’
Attribute	<i>muzukashii</i> ‘Difficult’, <i>yasashii</i> ‘Easy’
Synonym	<i>jiten</i> ‘Encyclopedia’
Action	<i>yomu</i> ‘Read’, <i>shiraberu</i> ‘Investigate’
Situation	<i>toshokan</i> ‘Library’, <i>honya</i> ‘Book store’

the number of participants is 50. The total number of associated words is approximately 280,000. When all of overlapping words are eliminated, the number of associated words is about 64,000.

### Proposed Method for Detecting Metonymies

To detect metonymic expressions in sentences, we use associative information between words in the Verb-ACD and the Noun-ACD. Our proposed method extracts attribute values of input sentences and detects metonymic expressions with decision tree learning. We first describe our basic idea, and then, the attributes of decision tree learning.

#### Basic Idea for Metonymy Detection

Semantic relations between metonymic expressions and their predicates seem to be more unnatural than that of literal expressions and their predicates. Hence, it is natural for humans to associate more literal expressions from predicates than metonymic ones. Our basic idea therefore is that the degree of word distances in the Verb-ACD and the Noun-ACD can express the measures of judging expressions as ‘Metonymic’ or ‘Literal’.

A method based on the basic idea is detecting metonymic expressions with associative information by using relations of two paths of synset nodes in the Japanese WordNet (Isahara, Bond, Uchimoto, Utiyama, & Kanzaki, 2008). One is the path from synsets of associated words to their hypernym synsets. The other is from synsets of each word in a sentence to their hypernym synsets. If there is a shared synset node between these two paths, the word in the sentence is regarded as a literal expression. On the other hand, it is possible to be a metonymic expression if there is no shared synset. Our system outline consists of four steps:

1. **Morphological and Syntactic Analyses.** The system analyzes an input sentence morphologically and syntactically by using McCab and CaboCha, respectively.
2. **Extraction of Associative Information.** From the results of morphological and syntactic analyses, the system extracts a predicate in the sentence and its modification relations. When the predicate is a verb or a verbal noun followed by *suru*, e.g., *taiho-suru* ‘arrest (verb)’ where *suru* added to *taiho* ‘arrest (noun)’, the shortest and the second-shortest associated words from a pair of the predicate verb

and a particle corresponding to the semantic relation in Table 2 are extracted from the Verb-ACD. If the sentence has more than one particle, the system extracts associated words from each noun with the particle. If the predicate is anything except a verb, two stimulus words of the noun as an associated word with the semantic relation Attribute in Table 3 are extracted from the Noun-ACD. In the same manner as the case with the predicate verb, these word distances are the shortest and the second-shortest ones between the predicate, i.e., the associated and the stimulus word.

3. **Extraction of Noun Information.** The system extracts synsets and hypernym synsets of all nouns in the sentence from the Japanese WordNet. These hypernym synsets are all synsets which the system obtains from nouns in the sentence to each third upper level for the synset hierarchy. If there are proper nouns in the sentence, it extracts each synset of properties which are from the result of the morphological analysis because the Japanese WordNet does not have enough synsets of proper nouns. For example, if one of the proper nouns in the sentence in Table 1 is *hanoi* ‘Hanoi’, the system extracts synsets and hypernym synsets of *chiiki* ‘LOCATION’ which is a property from the result of morphological analysis.
4. **Confirmation of Shared Synset.** By comparing synsets and hypernym synsets of the associated words with those of nouns or the properties of proper nouns in the sentence, the system confirms whether a shared synset node is between both paths of synset nodes. If there are one or more shared synsets, the system judges the noun as ‘Literal’. On the other hand, if there is no shared synset, the system judges it as ‘Metonymic’.

The system thus decides on the correct category, ‘Metonymic’ or ‘Literal’, of every noun in input sentences and can detect metonymies with associative information.

#### Metonymy Detection using Decision Tree Learning

We prepared attributes shown in Table 4 for the decision tree learning. These attributes are all factors obtained in the basic idea.

*Semantic\_relation* represents semantic relations corresponding to particles with nouns in sentences. In addition, one of its values ‘Noun’ was used when the predicate was not a verb. *Distance\_1st\_candidate* and *Distance\_2nd\_candidate* were the shortest word distance and the second one between the predicate and the associated word, respectively. *Number\_A\_synset* and *Num\_A\_hyponym* were the number of synsets of the associated words and the sum of hypernym synsets from the synsets for three upper levels, respectively. *Num\_N\_synset* and *Num\_N\_hyponym* were also the number of synsets of nouns in the sentence and the sum of hypernym synsets for three upper levels. *Num\_HN\_synset* and *Num\_HN\_hyponym* were the number of synsets of the noun’s hypernyms and the sum of hypernym synsets of the

Table 4: Attributes and values with decision tree learning.

Attribute	Description	Value
<i>Semantic_relation</i>	Semantic relations corresponding to particles with nouns in a sentence	Agent, Object, Source, Goal, Location, Tool, Noun
<i>Distance_1st_candidate</i>	The shortest word distance between the predicate and associated words	Continuous
<i>Distance_2nd_candidate</i>	The second shortest word distance between the predicate and associated words	Continuous
<i>Number_A_synset</i>	The number of synsets of associated words	Continuous
<i>Number_A_hyponym</i>	The sum of hyponym synsets from the associated words for three upper levels	Continuous
<i>Number_N_synset</i>	The number of synsets of nouns in a sentence	Continuous
<i>Number_N_hyponym</i>	The sum of hyponym synsets from the nouns for three upper levels	Continuous
<i>Number_HN_synset</i>	The number of synsets of hyponyms of nouns in a sentence	Continuous
<i>Number_HN_hyponym</i>	The sum of hyponym synsets of hyponyms of the nouns in a sentence	Continuous
<i>Match_node</i>	The degree of linked nodes from each synset of the associated words and the nouns in a sentence to a shared synset	None, Near, Middle-Near, Middle, Middle-Far, Far

hyponyms for two upper levels to equalize hyponym levels from initial synsets as above, i.e., three upper levels. Let *Match\_node* denote the degree of linked synset nodes from each synset of the associated words and the nouns in the sentence to the shared synset. By using the sum number of linked nodes, this degree was separated to the following six levels: ‘None’, ‘Near’, ‘Middle-Near’, ‘Middle’, ‘Middle-Far’, and ‘Far’. ‘None’ means that there was no shared synset, i.e., the noun was judged as ‘Metonymic’. ‘Near’ means that either of the synset of the associated word or that of the noun in the sentence was just the shared synset at least, i.e., the sum of linked nodes was 0 or 1. ‘Middle-Near’ means that the average of each node was 1, i.e., the sum of linked nodes was 2. ‘Middle’ means that the sum of linked nodes was 3. ‘Middle-Far’ means that the average of each node was between 2 and 3. ‘Far’ means that the average of each node was more than 3, i.e., the sum of linked node was more than 6.

## Experiment

To evaluate our method, we prepared a baseline system where the Goi-Taikei—A Japanese Lexicon (Ikehara et al., 1999) was used to automatically detect metonymies. We prepared test sentences with literal and metonymic expressions and evaluated our method by comparing its recall, precision, and F-measure rates with those of the baseline. In this section, we describe the baseline, test sentences, and the evaluation results.

### Baseline System

The baseline system consisted of syntactic structures and noun properties in the Goi-Taikei, which was used for detecting metonymies (Murata et al., 2000). It first selects a syntactic type of the predicate using its syntactic information in the Goi-Taikei after morphological and syntactic analyses of an input sentence. It employs the highest priority order of syntactic information in each predicate verb because this order

indicates an order of preference in the Goi-taikei. The preference order was defined in order to translate from Japanese to English or from English to Japanese (Shirai, Ooyama, Ikehara, Miyazaki, & Yokoo, 1998). The syntactic information on each verb is a set of syntactic type and noun properties, and expresses that each verb has nouns with a part of speech. The baseline system then obtains nouns in the syntactic information and their properties. These noun properties consist of some nouns and are expressed by the hyponyms and hyponyms in the noun semantic hierarchy. Finally, the system judges the word as ‘Metonymic’ if each word in the sentence does not belong to the noun’s hyponyms in the hierarchy.

### Test Sentences

We prepared 90 test sentences which consisted of 45 ones with metonymic expressions and 45 ones with literal expressions. As shown in Table 5, most of the former sentences were extracted from the previous studies (Murata et al., 2000; Yamanashi, 1988). The latter were extracted from newspaper corpora of the Mainichi Newspaper (‘93–’95 and ‘03–’04) and included words used in the metonymic sentences. In 90 test sentences, there were 113 nouns which both our method and the baseline judged as ‘Metonymic’ or ‘Literal’.

### Results and Discussion

To judge each noun as ‘Metonymic’ or ‘Literal’, we extracted attributes from 90 test sentences and constructed 113 cases. We trained 112 cases, tested the other case with the training data, and repeated this procedure in a round-robin fashion. By running 113 folds, each case was judged as ‘Metonymic’ and ‘Literal’. From Table 6, we can see that our method judged correctly 95 cases and the baseline system did 81 cases correctly. Our method showed higher accuracy (0.84) than that of the baseline. There was significant difference ( $p < 0.05$ ) between them. Here, the statistical difference was determined by McNemar’s test. The evaluation measurements

Table 5: Examples of test sentences (in Japanese).

Metonymic sentence (English translation)	Literal sentence (English translation)
<i>isshoubin-wo nonda</i> (Someone drank the issho-bottle.)	<i>isshoubin-wo saidan-ni oita</i> (He places the issho-bottle on the altar.)
<i>kasetsu-ga genri-wo setsumei-suru</i> (The hypothesis explains the elements.)	<i>kankeisha-ga setsumei-shita</i> (People involved explained that.)
<i>shirobai-ga ihansha-wo taiho-shita</i> (The police motorcycle arrested the criminals.)	<i>keisatsukan-ga hanzaisha-wo taiho-shita</i> (The police man arrested the criminals.)
<i>shikisha-ha sono-clarinet-wo waratta</i> (The conductor laughed at the clarinet.)	<i>jibun-wo waratta</i> (Someone laughed about oneself.)
<i>kao-wo soru</i> (Someone shaves own face.)	<i>hige-wo soru</i> (Someone shaves a beard.)
<i>atama-wo karu</i> (Someone clips own head.)	<i>tanbo-de ine-wo karu</i> (Someone mows rice plants in the paddies.)

Table 6: Accuracy in judging whether metonymic expressions or literal meanings. Asterisk indicates statistical significance over baseline. (\*  $p < 0.05$ )

	Baseline	Proposed method
Accuracy	0.72 (81/113)	0.84 (95/113)*

Table 7: Precision, recall, and F-measure rates in detecting metonymic expressions.

	Baseline	Proposed method
Precision	0.63 (31/49)	0.85 (33/39)
Recall	0.69 (31/45)	0.73 (33/45)
F-measure	0.66	0.79

were recall, precision, and F-measure calculated by using the numbers of correct detections above. Our method expressed higher recall (0.73), precision (0.85), and F-measure (0.79) than those of the baseline system as shown in Table 7.

The two main reasons for our method’s superiority are as follows. First, there were differences between our method and the baseline in the way that knowledge was used. As described previously, the baseline used the highest priority order of syntactic information in each predicate. The priority order in the Goi-Taikai was defined as preference to translate, so it seemed to express the order of frequency of its usage (Shirai et al., 1998). From these, the baseline system used the highest frequency of syntactical information of the predicates. On the other hand, information on the predicates which our method used was short word distances between them and their associated words in the Verb-ACD and the Noun-ACD. From the results, it seemed to be more suitable to use the associative information of predicates. The second reason is that separating stages of *Match\_node* was a good way to detect metonymies. Here, to investigate the detail of our method, we show the result of the decision tree learning in training 113 cases in Figure 1. As shown in the figure, *Match\_node* in ‘None’ or ‘Far’ was judged as ‘Metonymic’ and that in ‘Near’ or ‘Middle’ was done as ‘Literal’. As mentioned previously, ‘Far’ means that the average of each node is more than 3. There

```

Match_node in {None, Far}: Metonymic (32/5)
Match_node in {Near, Middle}: Literal (43/6)
Match_node = Middle-Near:
...Distance_2nd_candidate <= 2.74: Metonymic (3)
: Distance_2nd_candidate > 2.74: Literal (8)
Match_node = Middle-Far:
...Number_S_hyponym <= 19: Literal (22/4)
: Number_S_hyponym > 19: Metonymic (5)

```

Figure 1: Result of decision tree learning in 113 cases.

are more synsets of abstract nouns in higher levels hence it is natural to be judged as ‘Metonymic’ in ‘Far’ where the matching synset is at higher levels in the mean. On the other hand, it is also natural to be judged as ‘Literal’ in ‘Near’ or ‘Middle’. From these, the sum of both the synset node from associated words and that from nouns indicates the measures of detecting metonymies.

Given an example of the results, when an input Japanese sentence was *shikisha-ha sono-clarinet-wo waratta* ‘The conductor laughed at the clarinet.’ in Table 5, our method judged ‘clarinet’ as ‘Metonymic’ while the baseline could not. In the Verb-ACD, the associated words whose distances were especially short were *hito* ‘human’ and *telebi-bangumi* ‘TV program’. Therefore, it extracted these associated words, their synsets, and hypernym synsets from Japanese WordNet. It then compared them with ‘clarinet’ and its synset expressed by music instruments. Since the extracted words and their synsets did not match ‘clarinet’ and or its synset, the expression was judged as ‘Metonymic’. Meanwhile, the baseline extracted syntactic information of the following predicate verb ‘laugh’ from the Goi-Taikai: “N1 laughs at N2” where noun properties of “N1” and “N2” were *hito* ‘human’ and *asterisk* ‘all properties’, respectively. The property of ‘clarinet’ was *gakki* ‘instrument’ and belonged to “N2” whose property was *asterisk* ‘all properties’. As a result, the baseline system judged ‘clarinet’ as ‘Literal’. In general, we usually understand the meaning ‘The conductor laughed at the clarinet player’ when we read the sentence. Of course, it is not wrong syntactically that the conductor laughed at the instru-

ment of clarinet, but it is unnatural in daily conversations. Our method was closer to our associations in daily conversations and more appropriate to detect metonymies than the baseline. We therefore conclude that using associative information can improve computer's ability to detect metonymies as humans do.

However, our method incorrectly judged some literal expressions as 'Metonymic'. The reason was that some associated words in the Verb-ACD and those in their synsets in the Japanese WordNet were metonymies. Our method incorrectly judged some metonymic expressions as 'Literal' because the variety of associated words with the short word distances was sometimes too restricted. This small variety within the group of associated words could have led to a smaller range in the search space of the Japanese WordNet, leading to the tendency to detect too many metonymies.

### Summary and Future Work

We used the Verb-ACD and the Japanese WordNet to detect metonymic expressions in sentences with associative information. We found that our method has a higher accuracy of judging 'Metonymic' or 'Literal', recall, precision, and F-measure of detecting metonymies than those of the baseline that only uses syntactic and semantic information.

Future work includes detecting metonymies for the temporal contiguity and constructing a system for interpreting metonymic expressions. We would like to integrate them into our current detection method to improve our analysis of metonymy.

### Acknowledgments

This work has been partially supported by the Graduate School Doctorate Student Grant Aid Program 2011, Keio University. We would like to thank the students at Shonan Fujisawa Campus of Keio University for their participation in the association experiments.

## Abstract

We present initial work on a biologically and cognitively inspired model that may allow embodied agents to autonomously learn sequences of action primitives (forming an overall behaviour). Specifically, we combine a flexible model of sequence generation with a model of parietal mirror neuron activity. The main purpose is to illustrate that the approach is viable. Although further work is needed to improve the results sketched out here, the concept is sound and relevant both to efforts in modelling mirror neuron activity and enabling artificial embodied agents to autonomously learn sequences of action primitives.

**Keywords:** Behavioural sequence learning; Ordinal node model; Self-organising maps; Mirror neurons

## Introduction

We are concerned with the problem of generating sequences of action primitives which are flexible with respect to the precise time it takes to execute the different components (primitives) of the same sequence at different times. A thorough discussion of the issue is given, for instance, by Sandamirskaya & Schöner (2010). In a nutshell, part of the problem is that one cannot simply chain together the different primitives through, for example, simple Hebbian learning. Rather, mechanisms must exist for keeping track of the current location in the sequence, including ways of verifying that the current action has successfully completed or failed to complete. Sandamirskaya & Schöner (2010) describe a general framework which can address these issues and we briefly sketch the main points in the next section.

Overall, the aim of the work in the present paper is to combine said framework with a model of parietal mirror neuron activity (Thill et al., 2011) and to illustrate that such an approach is, in principle, viable. Importantly, since the mirror neuron model used here autonomously organises itself, the work proposed here may be relevant and helpful in designing artificial embodied agents that should autonomously learn sequences of actions and use them to predict actions of others.

## Sequencing via ordinal nodes and conditions of satisfaction

The gist of the framework by Sandamirskaya & Schöner (2010) is the existence of *ordinal nodes* which essentially count through the sequence. These nodes are implemented via coupled dynamical systems (see *Methods*), designed so that only one node can be active at a time. Upon completion of the element of the sequence represented by the active node, activation is passed onto the next node in the sequence. In their work (e.g. Sandamirskaya & Schöner, 2010; Sandamirskaya et al., 2011), the action primitives forming the sequence exist in the sensorimotor representation of an embodied agent, implemented using techniques from Dynamic Field Theory (Schöner, 2009; Spencer et al., 2009). This has the advantage that the sensorimotor representations of these primitives are stable (since they are essentially stable fixed-point attractors), which makes it particularly simple to link specific locations in the dynamic fields representing the sensorimotor space of the agent to specific ordinal nodes. Part of the challenge of the work presented in the present paper is to illustrate that the ordinal node system could also be attached to a representation with more noise and less stability than dynamic fields.

The decision that a given action primitive has completed is implemented a separate system (also exploiting dynamic fields) that checks for a *Condition of Satisfaction* (CoS). One of the open challenges here is the question of how to best learn the CoS for specific primitives (including identifying that the primitive has, for whatever reason, failed). It is not the purpose of the present work to address the open issues regarding the CoS - rather, we focus on combining the ordinal node model with a model of mirror neuron activity discussed in the next section.

## Mirror system sequences

One example of sequencing in biology is given by the hypothesised functioning of the mirror system. Without entering the debate on what higher-level cognitive abilities mirror

neurons may or may not be useful/essential for (see for instance Hickok, 2008; Rizzolatti & Sinigaglia, 2010, for such a debate), it appears that parietal mirror neurons in macaque monkeys organise into pools of neurons responding to specific motion primitives (*e.g.* a *reach* or a *grasp* but not both; Fogassi et al., 2005). It has then been hypothesised (*e.g.* Chersi et al., 2006) that these pools of neurons can be chained together to form sequences of simple, often-encountered actions (such as *reach-grasp-bring-to-mouth* for eating). Models on the basis of this hypothesis have proven useful, for instance, in putting forward theories unifying apparently conflicting results on interference and facilitation in action language processing (Chersi et al., 2010).

A particular model that specifically addresses the development of parietal mirror neurons has been previously presented by some of us (Thill et al., 2011). This model uses a self-organising map (SOM) to illustrate how a “blank” structure, through the organisational principles of SOMs can autonomously form an organisation whose activity resembles that of parietal mirror neurons.

The inputs to the model represent an arbitrary encoding of observed (or executed) motion primitives (*e.g.* based on changes in position per time step) and contextual information (including, for instance, affordances in the perceived scenery). These two components are sampled from two distinct spaces (of arbitrary dimensionality) and concatenated into a single input vector as required by standard SOM implementations (Kohonen, 1997). The model is trained on repeated presentations of all combination of motion primitives and contexts. After training, the model can be run on-line by continuously feeding it input vectors and some plasticity (allowing, for instance, the learning of new primitives) can be retained by not reducing the learning rate to 0 (albeit keeping it at a low level, see Thill & Ziemke, 2010).

The trained maps organise in a fashion remarkably similar to that of parietal mirror neurons (Fogassi et al., 2005): Within the map, different areas encode different action primitives (which could represent motions such as *reaching*, *grasping* or *bring-to-mouth*, similar to *e.g.* Chersi et al., 2006). Within the area encoding one such primitive, some nodes are active whenever the model input encodes that primitive. Others are active only if the action input additionally encodes a specific context in which the primitive is observed (usually sufficient to specify the most likely goal of the action, see Thill et al., 2011). The proportion of context-independent nodes is a direct consequence of the way inputs are represented (specifically, of the ratio between the maximal variability in encoding the primitives and contextual information respectively, called  $\beta$  in the model). Exploring how  $\beta$  (for which values between 1 and 5 cover most aspects of interest) affects the organisation of the maps revealed that, for  $\beta \approx 3.5$ , the proportion of context-independent nodes is similar to the corresponding neurophysiological data observed in the parietal mirror area of macaques (Fogassi et al., 2005).

## Combining models

Previous models of parietal mirror neuron activation tend not to address the timing aspect of the chains in much detail, focussing instead on merely linking the different pools forming a chain through hard-coding (Chersi et al., 2006, 2010) or, for instance, Hebbian learning (Erlhagen et al., 2007). With the exception of Chersi et al. (2010), these models do not take into account that the pools encoding the same primitive under different goals are not entirely distinct (Fogassi et al., 2005). Thill et al. (2011), whose main focus is the exact nature of this overlap between populations, do not specifically address chain formation at all.

The present paper therefore presents an augmented version of the model from Thill et al. (2011). Specifically, we now implement the learning of chains of primitives, using the approach of Sandamirskaya & Schöner (2010). This new model then allows us to address a number of open issues: to what extent is the ability to activate the correct (and only the correct) sequence of events (given the first element) affected by the overlap between neural populations? When observing an action primitive in an unknown context, is it possible to predict all possible chains this action could be part of?

These issues are relevant, both for our understanding of (in particular) sequences in mirror neuron activity and for the ability to endow artificial agents with similar abilities. If one subscribes to the hypothesis that mirror neuron activity helps us understand the actions of others (see Rizzolatti & Sinigaglia, 2010, for a thorough review and discussion), then the ability to predict the likely outcome of an action given the initial movement based on the resulting mirror neuron activity is a desirable ability. This includes the ability to autonomously learn sequences of actions as well as the ability to both correctly identify a sequence if the context is clear and predict all possible sequences if the context is ambiguous (for instance, a familiar gesture observed in a completely new context).

## Methods

### Overall model design

The model (Fig. 1) is composed of a self-organising map which is meant to represent parietal mirror neuron activation (Thill et al., 2011) and an ordinal node model for sequence learning (Sandamirskaya & Schöner, 2010). The activity over time in the SOM is used (1) to train the sequence learning model, (2) to activate learned sequences and (3) to provide the input necessary to move from one sequence element to the next. It therefore combines the idea of chaining pools of neurons (*e.g.* Chersi et al., 2006) with the flexible execution of sequences provided by the ordinal nodes model of Sandamirskaya & Schöner (2010).

### Self-organising maps as a mirror system

The self-organising maps used in this paper are in essence identical to those used by Thill et al. (2011) and are trained in the same manner. The only difference is that the previous maps explicitly dedicated part of their space to the theoretical

Figure 1: **Overall model architecture.** Activation in the SOM feeds into the ordinal nodes, both to activate the sequence (green) and to move between sequence elements (red) if the CoS is fulfilled (blue). Connections between the SOM and the nodes are bidirectional; node activity can thus also be used to activate regions in the SOM (omitted in the figure for clarity).

possibility of learning motion primitives from a second limb (see Thill & Ziemke, 2010, for details). Since that is irrelevant here, the present maps are trained assuming the need to represent just one limb. The trained maps therefore represent, as before, five motion primitives observed under two different contexts. They behave as described in the introduction: input vectors consisting of a concatenation of observed/executed motion encoding and contextual information are continuously fed to the map. Depending on the previously discussed ratio  $\beta$ , some nodes of the map will be active regardless of the contextual information whereas others will be sensitive to the latter (see Thill et al., 2011, for a complete discussion of the definition of activity).

### Ordinal node model

The ordinal node model used here largely follows Sandamirskaya & Schöner (2010) and is described by the following equations:

$$\begin{aligned} \tau \dot{d}_i(t) = & -d_i(t) + h_d + c_0 f(d_i(t)) \\ & - c_1 \sum_{i' \neq i} f(d_{i'}(t)) + c_2 f(d_{i-1}^m(t)) \\ & - c_3 f(d_i^m(t)) - c_{CoS} I_C(t) + c_{in} I \end{aligned} \quad (1)$$

$$\begin{aligned} \tau \dot{d}_i^m(t) = & -d_i^m(t) + h_m + c_4 f(d_i^m(t)) \\ & - c_5 \sum_{i' \neq i} f(d_{i'}(t)) + c_6 f(d_i(t)) \end{aligned} \quad (2)$$

where  $d_i$  refers to the activation of the  $i$ th ordinal node (and  $d_i^m$  is the associated memory node needed for proper

Figure 2: **Sequences in the SOM.** Shown are the activation of three primitives (columns) seen under two different contexts (rows) for a map with  $\beta = 3$ . Dark regions indicate most activity and are clearly in different locations for different primitives. For the same primitives in different contexts, similar regions are activated but the overlap between the most active neurons in each context is limited (see Thill et al., 2011, for a thorough discussion).

functioning, see Sandamirskaya & Schöner (2010) for details),  $f(\cdot)$  is a sigmoidal nonlinearity and the constants in the present implementation are chosen as:  $c_0 = 7.2$ ,  $c_1 = 3.6$ ,  $c_2 = 4.8$ ,  $c_3 = 0.8$ ,  $c_4 = 4$ ,  $c_5 = 2$ ,  $c_6 = 2.6$ ,  $c_{in} = 0.1$ ,  $c_{CoS} = 0.2$ ,  $h_d = -5$  and  $h_m = -2$ . A detailed discussion of the functioning of the model is given by Sandamirskaya & Schöner (2010). We deviate in two minor aspects: (1) The term  $c_{in}I$  is added and provides an external input (obtained from the activity in the SOM described above). This is only used at the beginning of a sequence to activate the first ordinal node. (2) We simplify the Condition-of-Satisfaction (CoS) aspect. In the original model, this is given by an additional dynamic field which is able to “perceive” that the CoS has been reached. Here, the inhibitory activation is obtained from the same SOM that would provide  $I$  for the activation of the first node, which simplifies the design of the model. Since the model is not actually implemented in an agent, there is also no point in devising a sophisticated “perception” of the CoS here. Rather, the CoS is presumed fulfilled after a randomly chosen number of time-steps and the inhibitory activation released to the ordinal model, thus moving the model onto the next element of the sequence. This is acceptable for the present purposes since the point here is to illustrate the learning of sequences, not the ability to autonomously detect that an element of a sequence has completed (or failed to complete). An implementation of this model in an agent would of course need to address this aspect in more detail.

## Task and learning

For each  $\beta$  value between 1 and 5 (in increments of .5), 100 maps have been generated. Each map is activated manually with a series of input vectors which simulate a sequence of 3 motion primitives being executed first in one context and then in another (see Fig. 2 for an example of two sequences). Two sets of ordinal nodes are used to learn these two sequences. Learning is achieved during manual activation of the map by clamping the relevant ordinal node to an active state and then using simple Hebbian learning to train weights between this node and all neurons in the map (with normalised activation). After training, any weights below a threshold of 0.5 are set to 0 to allow only the SOM nodes with the strongest activation to connect with the relevant ordinal nodes.

Of particular interest are the following questions: Will both sets of ordinal nodes correctly activate if the SOM activity is that of the first element of their respective sequences? Also, will a set of ordinal nodes trained on the first sequence remain *inactive* if the SOM activity represents the first element of the second sequence (and vice versa)? Illustrating these behaviours would confirm good performance of the model given that sequences are correctly activated if and only if the map activity corresponds to their first element. It should be remembered at this point that map activity is noisy and fluctuates over time - the task is therefore not trivial.

An additional interest is the behaviour of the model in case of ambiguous contextual information. As discussed in the introduction, this could correspond to observing a familiar primitive in an unfamiliar context and predicting what the likely outcome of the action could be. It is of course a matter of debate what the exact behaviour of the model should be in this case; one could for instance argue that it should depend on how similar the unfamiliar context is to previously encountered ones. Here, we simply investigate the behaviour if the vector encoding contextual information is truly ambiguous, namely by corresponding to the point in the input space whose coordinates are equidistant from the subspaces encoding all known contexts. In other words, the ambiguous context encoding vector cannot be uniquely assigned to any previously encountered case. We simply postulate that, in the absence of any information that could favour either of the chains, the desirable behaviour of the model is to activate both, essentially predicting that both behaviours are equally likely.

## Results

### Correct activation/non-activation

For each value of  $\beta$ , 100 sets of 2 sequences have been learned. Per set, the sequences differ only in the context in which they have been executed. As  $\beta$  increases, the proportion of neurons active in one but not both of the contexts decreases (Thill et al., 2011). It can therefore be expected that the basic task of correctly activating a sequence if the map activity corresponds to its first element (and not activating said sequence if the contextual information is that of the sec-

Figure 3: **Correct activation/non-activation.** Dark bars indicate the proportion of cases in which presenting the first element of a sequence correctly triggered the sequence. Light bars indicate the proportion of the cases that correctly trigger which correctly remain silent if the first element presented has the same motion primitive but different contextual information.

ond sequence) becomes harder as  $\beta$  increases. This is indeed what we find (see Fig. 3). Specifically, it is possible, in most cases, to correctly activate a sequence by presenting its first element in map activation (although it does fail on occasion, likely due to the noisy map activity). Importantly, this is independent of  $\beta$ , which is expected. The light bars in Fig. 3 then show how many (proportionally) of the sequences correctly activated by their own first element also remain silent when the first element of the second possible sequence is presented instead. As expected, this number decreases over time but remains over .5 in all cases.

However, this measure iterates over sequences that are correctly activated (or not); it does not measure the number of maps for which both sequences are correctly activated (or not). The evolution of this proportion is shown in Fig. 4 (black bars) and is decreasing more dramatically as  $\beta$  increases. At the same time, it should be noted that for e.g.  $\beta = 4$ ,  $\approx 60\%$  of nodes in the SOM encoding a given primitive are active independent of context (leaving only 20% capable of uniquely identifying each of the contexts).

### Correct behaviour under ambiguous context

The second interesting question was whether both sequences would be activated by the first motion primitive shown in a perfectly ambiguous context. Considered independently of the performance on the previous task, we find that a large number of models indeed activate both sequences given an ambiguous context. In particular, we find that this proportion increases with  $\beta$  (from 0.4 to  $> 0.9$ ), likely due to the increasing number of neurons which are active irrespective of con-

Figure 4: **“Perfect” models**. Black bars indicate proportion of cases in which the same model activates the correct sequence for each of the two learned sequences if presented with the first element of each sequence and does not activate the wrong sequence. Light bars indicate the proportion of cases fulfilling the first condition which also correctly activate both sequences if the contextual information is ambiguous

text.

This illustrates the expected effect of  $\beta$ : as the distinction between contexts diminishes, activation of both sequences is facilitated. However, this measure can again be seen as being a bit too general since there is not necessarily anything special about activating both sequences if the same model failed to *not* activate a sequence when primed with the first element (including the contextual information) of the second sequence. The more interesting question is therefore simply how many of the models that correctly behave given the learned sequences (black bars in Fig. 4 *also* behave as expected given the first primitive under an ambiguous context (within the context of this work, we can call these models “perfect”, since they fulfil all the expectations set out to them). Surprisingly, this proportion appears to be independent of  $\beta$  (light bars in Fig. 4), although it has to be kept in mind that for  $\beta \geq 3$ , the number of models which fulfill the first condition is rather low.

In other words, if a model is capable of correctly activating the relevant sequence (and only that sequence) given a full first element of that sequence, it is likely to *also* activate both sequences if given the first primitive under an ambiguous context. This is the most significant result in the present paper: although it is increasingly difficult to find a model which will correctly activate its sequences given the first element as  $\beta$  increases, it is then much easier to find a model which can also activate both sequences in the case of perfectly ambiguous contextual information.

## Discussion

### Insights from the model

Most of the results shown have their main purpose in illustrating that the model works as expected, including the increasing difficulty in obtaining “perfect” models as the  $\beta$  values of the underlying maps increase. The exact extent of this increase in difficulty is hard to judge from the work presented here as several aspects can be improved. First and foremost, the parameters for the ordinal nodes model are set independently of  $\beta$ , even though  $\beta$  has a rather significant effect on the input into the ordinal nodes and therefore the behaviour of the sequences. The fact that it was possible at all to create successful models across the entire range of  $\beta$  values underlines the potential of the approach. In future work, however, the focus would have to be on  $\beta$  values around 3 – 3.5, since these are the values for which the activity in the SOM most resembles that observed by Fogassi et al. (2005) in parietal mirror neurons (Thill et al., 2011).

The self-organising maps themselves are randomly generated; nonetheless it seems that some are more suited for a combination with an ordinal nodes model than others (since some “perfect” models were found even for  $\beta = 5$ , although the number was very low) and more work would be needed to investigate what features of these maps, if any, facilitate the task. Insights into this question could prove very valuable in more general future work combining the ordinal node model with sequences that are generated in systems which do not offer the “nice and clean” activation patterns of dynamic fields.

The connections between the activity in the map and the ordinal nodes are learned with a simple general Hebbian learning approach and the only transformation of the map activity consisted of a simple normalisation. Again, this is about the simplest approach imaginable and it is likely that improvements, including possible non-linear transformations of map activity, can lead to a higher proportion of “perfect” models for larger values of  $\beta$  (in particular of course for  $\beta \in [3, 3.5]$ ).

The most interesting result in the present paper was that the largest difficulty resided in finding models which perform as expected when started with a first element from either learned sequence and not, as one might have expected, in finding such a model that *also* perform correctly on the prediction task. This is encouraging as it illustrates that the concepts of using a combination of our previous SOM models of mirror neurons and the ordinal node model has potential, not just for generating the sequences one wishes to generate but also for predicting what sequences observed actions can be part of; this both in the case where the contextual information strongly favours one of the learned sequences and when the contextual information is perfectly ambiguous.

Again, there is a need for future work in this aspect. It seems reasonable (for the purposes of predicting likely sequences an observed primitive could belong to) to expect that a perfectly ambiguous context should activate all candidates but it is less clear - and beyond the scope of what can be

achieved in this space - what should happen if the context is merely ambiguous but closer in input space to some known contexts than others. Should the model simply activate the most likely sequence or would one prefer a mechanism that could attach a confidence value - indicated for instance by the time it takes the first ordinal nodes of all candidate sequences to activate - to indicate most and least likely sequences?

### Overall relevance

The work presented here is relevant for at least two areas. First is the modelling of mirror neurons as it is one of the first attempts to explicitly include the idea that executing the same action primitive at different points in time can lead to different durations, thus going beyond simple Hebbian-type associations directly between the primitives forming an overall action sequence (e.g. Chersi et al., 2010). Second, by modelling the specific organisation of parietal mirror neurons (which can develop autonomously, see Thill et al., 2011) and using that as an input to the ordinal node system, the model may provide a way for an artificial agent to learn sequences of primitives online and autonomously, which is still an open challenge (Sandamirskaya & Schöner, 2010).

The practical future applications are thus primarily in the design of future artificial cognitive systems; however all aspects of the model are inspired by biology; any implementation of the model could thus also be relevant to improve our understanding of the analogous biological systems.

### Conclusion

We presented an initial implementation of a mirror system activity model augmented with a framework for generating sequences. The main purpose was that it is in principle feasible to use the ordinal node framework to this effect. Although further work is needed to improve the quality, it was possible to show that the model can learn sequences based on the noisy SOM activity as well as correctly predict the likely sequence an observed initial primitive can belong to (including predicting both if both are equally likely). Since the SOM autonomously organises, the model presented here may be a viable candidate for autonomous sequence learning using the ordinal node framework (Sandamirskaya & Schöner, 2010).

## Abstract

Fuzzy memory theory extends fuzzy set theory to the case of imperfectly performing memory devices. In fuzzy set theory, the key concept is that of graded set membership. The degree to which an item belongs to a set is specified by a continuous function. Fuzzy memory theory is organized around the analogous concept of *graded recall*. Items stored in a fuzzy memory are associated with cues, such that each item is recalled by provision of the corresponding cue. But unlike conventional memory (where cues are typically addresses) the recall process may vary in its degree of error. The item produced may embody missing information. The capacity of a fuzzy memory is then measured in terms of the net information content of recalled items. The theory has potential applications for new forms of technology, but also for the study of cognition. In particular, it can be the means of formalizing the properties of error-prone natural memory mechanisms. It can also supply a non-circular explanation for similarity-based category formation.

## Introduction

Since its innovation nearly half a century ago (Gottwald, 2010), fuzzy set theory has become an essential tool of analysis in a wide range of disciplines (cf. Zadeh, 1965, 1976, 1982). In essence, the theory is a generalization of the classical theory of sets, in which set membership becomes a continuous rather than all-or-nothing criterion. The framework is particularly of use in contexts where set membership has a probabilistic character. There have been many applications in cognitive science. For example, the theory has been used for analysis of concept combination and feature emergence (Osherson and Smith, 1981, 1982; Zadeh, 1965, 1976, 1982). In this approach, concepts are deemed to represent fuzzy sets of objects, on which basis combinational concepts can be seen to represent the (fuzzy) intersections of the sets associated with the constituents (Murphy, 2002).

The present paper extends the theory of fuzzy sets to the case of memory. In fuzzy set theory, we assume an item can be a member of a set to a greater or lesser degree. In the proposed extension, it is the degree to which items are recalled that is variable. Information theory (Shannon, 1948; Shannon and Weaver, 1949) provides the means of measurement. The imperfection with which a particular item is recalled can be related to the amount of missing information (i.e., uncertainty) the recalled item exhibits.

Formally, a fuzzy memory device is considered to be a function from cues to items. But the items produced by the memory have to be distinguished from the reference items that are deemed to be stored. The behaviour of a fuzzy memory device is thus characterized as

$$f : C \rightarrow X'$$

where  $C$  is the set of cues,  $X$  is the set of reference items that are considered to be stored and  $X'$  is a set that replaces each member of  $X$  with the item recalled.

The storage capacity of the device then depends on the information content of the recalled items. This is denoted  $I(X')$ . But in calculating capacity, we must also take account of  $C$ , the set of cues. If this is not done, a function that simply copies its argument has the potential to exhibit an arbitrarily large storage capacity. The capacity of a fuzzy memory device is thus defined to be the *net* information content of recalled items. This is the information content of the reference items less the content of the keys and the information that is lost in recall. Formally, the capacity of fuzzy memory  $f$  is

$$I(X') - I(C)$$

where  $C$  is the set of cues used to elicit members of  $X'$  by  $f$ .<sup>1</sup>

In fuzzy set theory, the constituents of a set are characterized using a continuous function. This allows any degree of set membership to be specified. Extending the idea to the case of memory, we require a probabilistic model for the variables on which reference items are constructed. These are termed *base variables* below. A model that imposes a distribution on each variable will not suffice, since it cannot accommodate information losses involving specific variable combinations. A fuzzy memory is therefore considered to be a *composite* of distributions, in which each distribution applies either directly or indirectly to one or more base variables. Information losses arising in the recall of base-variable combinations are then accommodated.

This constituency can be formalized in a recursive way. Letting a distribution be considered *contributory* if it

---

<sup>1</sup>The word ‘memory’ refers to fuzzy memory in all cases.

applies directly to a base variable, or to a variable whose values themselves designate contributory distributions, we can characterize the constituents of memory  $f$  thus:

$$f = \{P \mid \text{contrib}(P, f)\}$$

In this formula,  $\text{contrib}(P, f)$  is true just in case distribution  $P$  applies either directly or indirectly to any base variable of  $f$ . Variables that mediate indirectly applying distributions are termed contributory variables. This distinguishes them from the base variables on which reference items are constructed.

A storage criterion for fuzzy memory can then be formalized. Fuzzy memory  $f$  is deemed to store some item  $x$  if  $x$  can be probabilistically reconstructed from  $f$ 's distribution composite. The informational requirements are as follows. The reconstruction must reconstitute the original item with measurable (but potentially zero) loss of information, and this loss must be less than the information required to specify the cue for the reconstruction. An item is deemed to be stored, then, just in case it can be reconstructed with a net gain of information. The degree of recall is the net gain obtained.

The degree to which an item is recalled by a fuzzy memory is analogous to 'grade of membership' in fuzzy set theory. The evaluation is formalized as follows. The grade of recall for some item  $x$  given some cue  $c$  is

$$r(x, c) = I(x') - I(c)$$

where  $x'$  is the device's probabilistic reconstruction of  $x$ , and  $x'$  satisfies the requirement of being derivable from  $x$  by elimination of information. The definition of  $I(c)$  depends on how cues are constituted (see below). Given there are  $k$  bits of content in each base-variable instantiation, the value of  $I(x')$  is

$$I(x') = \sum_i k - H(x'_i)$$

where  $H(x'_i)$  is the entropy of the distribution derived for the  $i$ 'th variable of  $x'$ .

## Illustrations

To illustrate the use of fuzzy memory, it is convenient to look at the case of 1-bit devices. These are simple assemblies in which base and contributory variables are all binary. Variable values are the digits 1 and 0, each of which has an information content of 1.0 bit. An advantage of this type of device is that it is particularly easy to represent as a tree diagram (cf. Figure 1). It also allows a simple cueing protocol, in which each cue comprises some subsequence of the variable evaluations required to render a fully deterministic reconstruction. In this context, a cue is a sequence of reconstruction constraints.

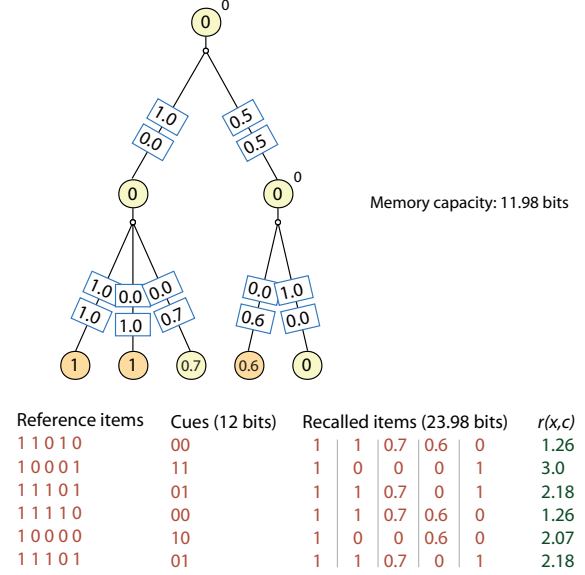

Figure 1: Recall performance of a 1-bit memory.

Consider Figure 1. This is a 1-bit fuzzy memory constructed for the reference items shown in the lower, left part of the figure. The tree structure in the upper part of the figure represents the composite of distributions. Notice this has two levels of construction. These are termed level 1 and level 2. Circles in the bottom row represent base variables. Circles elsewhere represent contributory variables. The digit seen within a circle is the value (or more generally distribution) the variable acquires in recall of the first reference item. Finally, the arcs leading down from each circle show which distributions are designated by which values of the relevant contributory variable.

Consider the leftmost contributory variable at the first level of the composite. By following the attached arcs downwards, we see that each value of this variable designates distributions applying to the three leftmost base variables. All distributions being over the values 0 and 1, only the probability applying to 1 is specified. Thus a value such as '0.6' is shorthand for the distribution  $\langle 0.4, 0.6 \rangle$ , i.e., the distribution that gives probability 0.4 to a value of 0 in the designated variable, and probability 0.6 to a value of 1.

Also of note is the way the distributional values are arranged. Over each set of arcs, we have two rows of boxes. Lower boxes contain distributions designated by a value of 0 in the contributory variable; upper boxes represent distributions designated by a value of 1. Applying these conventions, it should be possible to interpret all the distributions of Figure 1. For example, looking at the bottom, left part of the structure, we see that a value of 0 in the rightmost variable at level 1 designates a distribution on the third base variable which gives a probability

0.7 to the value 0.

The listing in the lower part of the figure portrays the behaviour of the device for the six reference items. (Distributions on variables are those obtained during recall of the initial item.) Each row shows the degree to which a particular item is recalled by its cue, with the associated recall grade  $r(x, c)$  appearing on the far right of the figure. As noted, each cue in a 1-bit memory is some subsequence of the disambiguating values required to produce a fully determined reconstruction. For the initial reference item  $\langle 1\ 1\ 0\ 1\ 0 \rangle$ , we have the cue 00. The initial digit in this sequence resolves the initial ambiguity in the reconstruction: i.e., it supplies the value 0 for the root contributory variable. The second digit resolves the next ambiguity arising. This affects the rightmost contributory variable at level 1. This value is subject to the equiprobable distribution developed in the previous step. The variable acquires the value 0.

With the cue now exhausted, the reconstruction continues in an un-cued way. The first, second and fifth base variables then acquire implicitly deterministic values, i.e., distributions that embody no loss of information. Regarding the third and fourth base variables, we have the distributions  $\langle 0.3, 0.7 \rangle$  and  $\langle 0.4, 0.6 \rangle$  respectively. Adopting the previous convention for representing binary distributions, the recalled item is then  $\langle 1\ 1\ 0.7\ 0.6\ 0 \rangle$ . There is of recall of 1.26 bits. This is the information obtained from the five bits of the reference item after deducting the two bits of the cue, and the 1.74 bits eliminated by the two information-losing distributions. Summing recall values for all six reference items, the total capacity of the memory is found to be 11.98 bits.

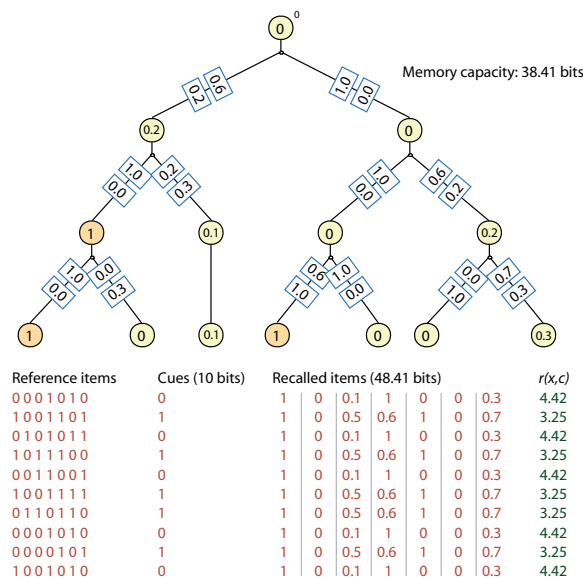

Figure 2: 1-bit memory with a capacity of 38.41 bits.

A more complex illustration of the 1-bit memory is provided by Figure 2. This is a fuzzy memory for the 10 reference items shown on the left. In this example, reference items are defined in terms of seven base variables rather than five. Contributory variables exist at three levels of construction rather than two. The cueing protocol remains the same. But, here, cue sequences comprise a single digit, meaning they supply values for the root variable only. The main part of the construction process thus proceeds in an un-cued way, with the result being a noticeable increase in the uncertainty of what is recalled. However, with the informational cost of cues at a low level, the memory capacity remains relatively substantial.

## Applications in cognitive science

Fuzzy memory theory formalizes a statistical form of memory in a way that reflects fuzzy set theory. Applications of a technological nature are one possibility. But might there also be applications in cognitive science? One way the theory could be used involves natural forms of memory. Human memory is notoriously error-prone, perfect recall being more the exception than the rule. There may be potential, then, for using the framework as a way of theoretically modeling human and other biological forms of memory.

Another possible application involves modeling development of categorical and conceptual representations. It is widely believed that such behaviours are at the heart of cognition (e.g. Harnad, 2005) and that categories are constructed so as to group entities by similarity (Machery, 2009). But it remains a considerable challenge to explain why this should be the case (Murphy, 2002). The temptation is to say that categories are formed as a *result* of the ways in which similarities are identified. Unfortunately, this makes no sense if the way we identify similarities depends on the category representations we bring to bear. With similarity being used to explain both why an entity is assigned to a certain category, and also why that category exists in the first place, such theories are placed ‘in the perilous position of using explanations which presuppose the very notions that they attempt to explain’ (Hahn and Chater, 1997, p. 84).

Fuzzy memory theory has the potential to address this dilemma. The critical factor affecting performance in fuzzy memory is the degree to which recalled items resemble reference items. The more closely each recalled item approximates its referenced counterpart, the less information is lost and the greater the capacity of the memory. But notice that recall loses less information if distributions deploy more extremal probabilities (i.e., probabilities closer to 1.0 or 0.0). At the same time, distributions must fulfil the function of modeling the referenced items; i.e., they must be the means of constructing valid approximations.

Figure 3: 1-bit fuzzy memory interpreted as a structure of categories.

Combining these two observations, we see how an implicit similarity preference can arise. The distribution-composite of a fuzzy memory divides the reference data into implicit groupings based on variable subsets. Each of these groupings is then implicitly subdivided into two parts by the (binary) evaluations of the contributory variable involved. More memory capacity is obtained if within-group similarity is maximized, since this is the basis for achieving more extreme probabilities. Distribution composites that group by similarity thus yield relatively greater memory capacity. On the assumption that human memory can be formalized under the fuzzy memory model, the disposition to construct similarity-based categories would then be explained in a non-circular way. It would be seen as a strategy for *increasing* memory capacity.

The schematic of Figure 3 illustrates the idea in more intuitive terms. (The corresponding informational assessments appear in Figure 4.) This memory is constructed to represent the reference items shown in the lower, left part of the figure as usual. But all the variables of the memory are here seen as representing categories. The assumed domain is that of food concepts, such as COOKABLE and DOUGH. Each contributory variable has two labels. These name the categories that are represented by the two values of the variable, with the category represented by a value of 1 appearing above the category represented by a value of 0. The value 0 in the leftmost contributory variable at level 1, for example, represents the FRUIT category, while the value 1 in this variable represents NUT.

The distributions in the composite fulfil their key function of modeling the reference items. But notice how they also mediate similarity-based groupings. FRUIT can be seen to represent a group that includes all FLESHY items, some of which are COOKABLE.

Reference items	Cues (9 bits)	Recalled items (13.75 bits)				$r(x,c)$
0 1 0 1	0	0	0.5	0.2	1	1.27
0 1 1 0	0	0	0.5	0.2	1	1.27
0 1 1 1	0	0	0.5	0.2	1	1.27
1 0 1 1	11	1	0.4	0.2	1	0.3
1 1 1 1	11	1	0.4	0.2	1	0.3
1 0 1 0	11	1	0.4	0.2	1	0.3

Memory capacity: 4.75 bits

Figure 4: Graded recall using implicit food categories.

SPONGE represents a group that includes all cases of MIX, most of which are HIGHFAT. These fuzzy groupings then become the means of constructing higher-level categories such as PIE. At this level too, the structure can be viewed as exploiting similarities, although here they reflect the way instances of PIE incorporate (manifestations of) PASTRY and FRUIT.

On this interpretation, the distributions of the composite are akin to the prototype representations envisaged by Rosch and others (e.g. Rosch, 1973; Hampton, 2000). The difference is that here they are deployed at multiple levels of description, and in a way that gets around the problem of prototype compositing (Osherson and Smith, 1981; Prinz and Clark, 2004; Connolly et al., 2007). The construction of similarity-based groupings comes to be seen as a way of increasing the capacity to remember certain data. Exploitation of similarity is explained as a way of increasing the capacity of memory.

## Concluding comment

Inspiration for the idea of graded recall comes from the idea of graded set membership. This is the key concept in fuzzy set theory. What lies behind the operationalization of the idea is more obviously information-theoretic in nature: assessing degree of recall involves measurement of information loss. Fuzzy memory theory thus combines two distinct areas of theoretical analysis into a hybrid framework. This is found to have applications of a cognitive nature when note is taken of the ways the framework can model error-prone memory, and the development of categorical forms of representation.

## Abstract

Recent literature in the cognitive sciences has demonstrated that cognition is fundamentally embodied. For instance, various studies have shown that semantic knowledge about the human body correlates with spatial body representations, suggesting that such knowledge is embodied in nature. An alternative explanation for this finding comes from the Symbol Interdependency Hypothesis, which argues that perceptual information is encoded in language. We demonstrated that the findings that can be explained by an embodied cognition account can also be explained through statistical linguistic frequencies. Co-occurrence frequencies of names for common body parts correlated with experimental findings from adults and children. Moreover, the position of the body parts was predicted on the basis of statistical linguistic frequencies. These findings suggest that language encodes embodied information.

**Keywords:** embodiment; statistical linguistic frequencies; symbolic cognition; embodied cognition; conceptual processing; symbol interdependency.

## Introduction

Over the last decade the notion that cognition is fundamentally embodied has dominated the cognitive sciences (Glenberg, 1997; Goldstone, & Barsalou, 1998; Barsalou, 1999; Lakoff & Johnson, 1999; Zwaan, 2004; Pecher & Zwaan, 2005; Semin & Smith, 2008). The central argument in theories of embodied cognition is that our minds co-evolved with our bodies, especially the sensory motor system, and that cognitive processes therefore heavily rely on perceptual simulations. This argument is in sharp contrast with a computational symbolic approach to cognition. Views of symbolic cognition suggest that meaning can be derived from linguistic context (Landauer & Dumais, 1997). In other words, instead of mental reenactment, mental representations can be seen as internal

structures of symbolic concepts and do not necessarily have a direct relation to perceptual states (Fodor, 1975; Pylyshyn, 1984).

There is a large body of literature that finds evidence that cognition is embodied. Studies have shown that processing within modalities is faster than having to map across modalities (e.g., Marques, 2006; Pecher, Zeelenberg & Barsalou, 2003; Spence, Nicholls & Driver, 2000). Language comprehension seems to be influenced by action representations primed in experimental tasks (e.g., McCloskey, Klatzky, & Pellegrino, 1992; Zwaan, Stanfield & Yaxley, 2002), and visual representations get activated during language comprehension. Perceptual feature characteristics that have affected language comprehension include orientation (Stanfield & Zwaan, 2001), temporality (Zwaan, Madden & Whitten, 2000), visibility (Rapp & Horton, 2003), spatial configuration (Louwerse, 2008; Zwaan & Yaxley, 2003), modality (Louwerse & Connell, 2011; van Dantzig et al., 2008), direction (Glenberg & Kaschak, 2002; Kaschak et al., 2005), or location (Šetić & Domijan, 2007).

Several embodied cognition studies have shown a relation between the meaning of words and their spatial configuration when presented on the screen. For instance, when words for concepts in the air, such as birds and insects, are presented in the upper half of a screen, participants respond faster than when the same words are presented in the bottom of the screen, with a reverse effect for words referring to concepts on land or in the ocean (Šetić & Domijan, 2007; Pecher, Van Dantzig, Boot, Zanolie, & Huber, 2010). Similarly, when word pairs such as *attic* and *basement* are presented vertically, one above the other, iconic pairs are processed faster than reverse iconic pairs, presumably because comprehenders perceptually simulate the position of these concepts (Zwaan & Yaxley, 2003).

Other studies have demonstrated that the vertical configuration of words on the screen and the meaning of those words can be extended to concepts we literally embody, such as body parts. For instance, understanding parts of our body is directly linked to the spatial representation of the human body, and that representation contains veridical information about the relative distance between body parts (Smeets et al., 2009; Struiksmā, Noordzij, & Postma, 2011; Van Elk & Blanke, 2011). When participants were presented with combinations of concepts that represent body parts, such as *head-neck*, processing time was considerably faster when the embodied distance of those concepts was small, compared to concepts for which the distance is large, such as *head-toe*. Studies like these yet again show that embodiment explains cognition.

However, the question can be raised as to what extent the relation between body semantics and spatial body representations can only be explained by an embodied cognition account. This is an important question, particularly if other accounts are complementary to the embodied cognition account.

We have argued for one such account in a number of studies. The Symbol Interdependency Hypothesis argues that language comprehension is both perceptual and linguistic in nature (Louwerse, 2008, 2011; Louwerse & Connell, 2011; Louwerse & Jeuniaux, 2010). That is, language comprehension is linguistic through statistical interdependencies between linguistic units and is perceptual through the references linguistic units make to perceptual representations. The Symbol Interdependency Hypothesis thereby makes an important prediction: language has evolved to become a communicative shortcut for language users and it encodes relations in the world. Accordingly, it is hypothesized that the findings attributed to an embodied cognition account can also be explained through statistical linguistic frequencies.

In a number of studies, we have shown that language indeed encodes perceptual information. Louwerse, Cai, Hu, Ventura, and Jeuniaux (2006) and Louwerse and Zwaan (2009) aimed to determine if language encodes geographical information by comparing city latitude/longitude with how often those cities appeared in a corpus. Louwerse, Cai, and Hutchinson (in press) have shown that these predictions are not limited to English, but can also be found in Chinese (predicting cities in China) and Arabic (predicting cities in the Middle East). Louwerse and Benesh (in press) have recently shown how using the *Lord of the Rings* trilogy the longitude and latitude for cities in the fictional Middle Earth can be predicted. The physical distance between cities was accurately estimated based upon statistical linguistic frequencies of cities, thus suggesting that language does encode (perceptual) geographical information.

The encoding of perceptual information in language goes well beyond geography. Louwerse and Connell (2011) have shown that the modality of a word (e.g., *sour*, *soft*, *loud*) can be predicted on the basis of statistical linguistic frequencies. That is, computational estimates on the modality of a word were less precise (visual/tactile, olfactory/taste, auditory) but equally as accurate as human estimates on the modality of words.

In addition to geographical predictions and modality predictions, Louwerse (2008) investigated whether iconicity of words can be predicted. Analogous to binomials such as *top and bottom*, *high and low*, and *up and down*, this study found that the iconic order of concepts such as *flower-stem* could indeed be predicted by simply looking at the order of the words.

It is relevant here to address the question whether these statistical linguistic cues are in fact used by comprehenders. Louwerse (2008) tested whether word pairs like *flower-stem*, presented vertically, yielded faster response times because participants were perceptually simulating the word pairs, or because of the word order (a linguistic factor). The findings demonstrated that the frequency of word pairs such as *flower-stem* (a perceptually realistic order) is significantly higher than word pairs *stem-flower* (a perceptually unrealistic order), and that linguistic frequencies explained response times at least as well as perceptual ratings.

The effect of perceptual and linguistic factors on cognitive processes is modulated by stimulus, cognitive task, and by duration of processing. Louwerse and Jeuniaux (2010) showed that linguistic factors best explained semantic judgments of word pairs, whereas perceptual factors best explained iconicity judgments of picture pairs. Furthermore, they concluded that linguistic factors dominated when participants were involved in shallow cognitive processes, and that perceptual factors dominated in deeper cognitive tasks. Louwerse and Connell (2011) extended these findings, showing that faster response times were best explained by linguistic factors, and slower response times were best explained by perceptual factors. These findings suggest that the relative employment of linguistic or perceptual representations changed as a function of the task, duration of the task, or stimulus.

In the following study, we determined whether embodied information – information about the distance between body parts – was also encoded in language. To test for this possibility, we conducted a computational linguistic study in which we calculated the co-occurrence of body part names and compared the statistical linguistic frequencies with the existing experimental data. We thereby hypothesized that body parts that are perceptually close together are placed in similar linguistic contexts, thereby allowing for accurate computational estimates on the position of the body part.

Figure 1. Body part similarity ratings of adults (A) and children (B) (Jacobowitz, 1973).

### Study 1

In previous research, Jacobowitz (1973) explored the development of language by comparing body part similarity ratings of five-year-old children, and adults. The 15 body parts used were: *Arm, body, cheek, ear, elbow, face, finger, foot, head, hand, knee, leg, mouth, palm, and toe*. Jacobowitz conducted four replicated multi-dimensional scaling analyses (RMDS), which simultaneously analyzed multiple matrices. The dimensional scaling illustrated that the five-year-olds grouped the head items, arm items, and leg items more similarly (see Figure 1B). The adults, on the other hand, grouped head terms together, but the other extremities were grouped by function (e.g., arm and leg (limbs) were more similar, finger and toe (digits) were more similar, etc.) (see Figure 1A). Jacobowitz found that the similarity ratings for body parts were hierarchical for both the children and adults.

In the current study, Jacobowitz's (1973) data was compared with findings from statistical linguistic frequencies. We calculated the frequency of first-order co-occurrences in the *Web 1T 5-gram* corpus (Brants & Franz, 2006). This corpus consists of one trillion word tokens (13,588,391 word types) from 95,119,665,584 sentences. The volume of the corpus allows for an extensive analysis of patterns in the English language. The frequency of co-occurrences of the 15 words was computed in bigrams, trigrams, 4-grams and 5-grams. For instance, the frequency of the words {*head, toe*} was determined by considering these words next to one another {*head, toe*}, with one word in between {*head w1 toe*}, with two {*head w1 w2 toe*} or with three intervening words {*head w1 w2 w3 toe*}. This method is identical to the one used in Louwerse (2008), Louwerse and Jeuniaux (2010), and Louwerse and Connell (2011).

The result of these computations was a 15 x 15 matrix of raw frequencies of co-occurrences, from which log frequencies were obtained. This matrix was submitted to an MDS analysis using the ALSCAL algorithm (see Young, Takane, & Lewyckij, 1978). For purposes of mapping the relative location of body parts, it is insufficient to simply obtain the co-occurrence frequencies in the Google corpus. The frequencies must be converted to x and y coordinates, and then a mathematical analysis performed to find the relative spatial location of the body parts. Multidimensional scaling (MDS) is a series of mathematical operations that can illuminate patterns within data that may not be

immediately recognizable with standard numerical output (Kruskal, & Wish, 1977; Blake, Schulze, & Hughes, 2003). MDS has been utilized to not only analyze similarity, but also to provide a graphical representation of those similarities. A Euclidean distance measure transformed the semantic similarities into dissimilarities, such that the higher the value, the longer the distance. Default MDS criteria were used with an S-stress convergence of .001, a minimum stress value of .005, and a maximum of 30 iterations. The fitting on a two-dimensional scale was moderate, with a Stress value = .21 and an  $R^2 = .86$ .

To do justice to the geometry of the 2D variables in Jacobowitz (1973), we used bidimensional regression analyses to compare the participants' estimates with the actual coordinates of the body parts. Tobler (1994) and Friedman and Kohler (2003) introduced bidimensional regressions in order to compute the mapping of any two planes under consideration. Whereas in a unidimensional regression each data point is shifted by intercept and slope, each actual and predicted value of the dependent variable are presented by a point in space, whereby vectors represent intercept and slope.

A bidimensional regression yielded a significant correlation between the frequency estimates and Jacobowitz's (1973) loadings on a two-dimensional plane for both the adult study,  $r = .66$ ,  $p < .01$ ,  $n = 15$ , and the child study,  $r = .63$ ,  $p = .01$ ,  $n = 15$ . To ascertain that these findings could not be attributed to accidental pairings of coordinates, we conducted a Monte Carlo simulation, randomly sampling each dataset 1000 times. The findings solidified the results, with no bidimensional relation between the statistical linguistic frequencies and Jacobowitz's (1973) adult data, average  $r = .23$  ( $SD = .12$ ),  $n = 15$  or child data, average  $r = .24$  ( $SD = .12$ ),  $n = 15$ . These findings suggest that statistical linguistic frequencies can explain data obtained from human participants.

In addition to the comparison between Jacobowitz's (1973) two-dimensional fitting, we compared a one-dimensional solution, using the first dimension of the MDS solution, with the location of the body part terms. The correlation between the location of the body part words and the computational estimates was again high,  $r = .6$ ,  $p < .001$ ,  $n = 15$ . The linear fitting between the computational estimates and the actual position is presented in Figure 2.

Figure 2. Multidimensional Scaling of 15 body parts from Jacobowitz (1973).

## Study 2

Van Elk and Blanke (2011) established a relationship for spatial position of body parts as well as the relative distance between them for native French speakers (see Table 1). In experiment 1, 38 body parts were assigned to nine categories dependent upon the distance from each other on the body (e.g., forehead/toe = 9; forehead/eye = 1). The words were then presented vertically in a congruent or incongruent spatial position (forehead/toe; toe/forehead). Subjects demonstrated increased RTs for larger distances, while position congruency did not seem to have an effect. Experiment 2 consisted of an iconicity judgment also using relative distance and congruency. However, in this experiment the words were not in the center of the screen as in Experiment 1, but arranged in varying distances from each other. There were significant main effects, as well as

an interaction, for the error rates. The RTs revealed there were main effects of congruency and distance, but no interaction was found.

We computed the log frequency of all combinations of the English body part words and compared the data with the Van Elk and Blanke (2011) distance data. Because the algorithm functions best with single words in a 2-5 gram window, we removed all words that require two words in English (*under arm*, *ring finger*, *index finger*, and *middle finger*). Moreover, no frequencies were found for *instep* and *pinkie* combinations, these words were removed from the analysis.

The correlation of the 32 x 32 word pair frequencies and the distances was significant,  $r = .35$ ,  $p < .001$ ,  $n = 1024$ , with higher frequencies yielding lower physical distances. This finding suggests that embodiment is encoded in language, such that the relative location of body parts can be estimated using statistical linguistic frequencies.

Next, we conducted analyses similar to the first study, whereby we did not use the raw frequency comparisons, but instead entered the  $n \times n$  matrix in an MDS algorithm and used the loadings of the body parts names as a comparison. To do justice to the one-dimensional plane Van Elk and Blanke (2011) used, the MDS solution was restricted to a one-dimensional solution. The fitting was moderate,  $Stress = .47$ ,  $R^2 = .50$ . When the loadings of the 32 body parts were compared with their physical distances, a strong correlation was found,  $r = -.76$ ,  $p < .001$ ,  $n = 32$ .

To determine whether these findings could in any way be attributed to accidental pairings of variables, we again conducted a Monte Carlo simulation, whereby correlations of the 1000 randomizations of the data were computed. The average correlation did not come close to the correlation obtained for the actual data, average  $r = .15$ ,  $p = .41$ ,  $n = 1000$ . As before, we plotted the position of the body parts and their corresponding words (Figure 3).

Table 1: Body part positions and categories (Van Elk & Blanke, 2011).

Word	Position	Loading	Cat.	Word	Position	Loading	Cat.	Word	Position	Loading	Cat.
hair	1	0.79	1	back	3	-1.15	10	palm	6	1.05	13

## Discussion

Recent literature has shown that perceptual information, such as geographical locations, modalities, and iconicity, is encoded in language. The current paper extended these findings by addressing the question whether language encodes (literally) embodied information: whether statistical linguistic frequencies can explain the relative location of different parts of the body. Results from two computational studies showed that such frequencies indeed can estimate the relative location of body parts. In study 1, we demonstrated that computationally derived values can explain human similarity estimates of body-parts. Study 2 similarly found that word frequencies can estimate physical distances between body parts. Both of these studies support the claim that language encodes body information.

We conclude that language inherently contains body part information, such that experimental results can be approximated computationally. This is in line with previous research that has demonstrated that language encodes geographical information (Louwerse & Zwaan, 2009), that it encodes modality specific information (Louwerse & Connell, 2011), spatial information (Louwerse, 2008), and social relations (Hutchinson, Datla, & Louwerse, in press). The current study adds to this literature and suggests that cognition is indeed both embodied and symbolic.

## Abstract

It has been claimed that a genuinely abstract number representation exists and is capable of representing the numerosity of any set of discrete elements irrespective of whether they are presented in visual or auditory modality. To test whether adults can compare large numerosities cross-modally as accurately as intra-modally, we measured Weber fractions and a point of subjective equality of numerical discrimination in the visual, auditory, and cross-modal conditions with use of a carefully controlled experimental procedure. Results showed distinct differences between the performances of the visual and the auditory condition in such way that numerical discrimination of the auditory sequence is more precise than that of visual sequence. Moreover, the performance of cross-modal trials differed among participants, with the exception that they were all worse than the auditory condition and that the number of visual stimuli was overestimated. Taken together, our findings implied that numerical discrimination of the auditory and visual stimuli mediates the modality-specific processes, suggesting that the numerical representation process can be complex of multiple stages.

**Keywords:** numerical discrimination; sensory modality; cross-modal comparison

## Introduction

Many studies supported the idea that humans possess innate neural mechanisms that generate approximate, not precise, numerical representations. Results from studies of numerical competence in infants, young children, and nonhuman animals have shown that the approximate numerical system is evolutionally old and is equipped early in human development (e.g., Cantlon & Brannon, 2006; Feigenson, Dehaene & Spelke, 2004; Hauser, Tsao, Garcia, & Spelke, 2003; Whalen, Gallistel & Gelman, 1999). Furthermore, converging empirical findings from several areas of cognitive neuroscience argue for biological determined mechanisms for approximate number representation (e.g., Nieder & Dehaene, 2009; Piazza, 2010). At the same time, certain researchers have prompted extensive investigation over the processes of number representation in the behavioral and neurophysical field (e.g., Kadosh, Lammertyn, & Izard 2008; Kadosh & Walsh, 2009).

One of the claims made by the proponents of abstract numerical representation is that the processing of approximate numerical representation is independent of

sensory modality. They argued that abstract numerical representation could genuinely be capable of representing the numerical of any set of discrete elements, whether they were presented in the visual or auditory condition (Barth, Kanwisher, & Spelke, 2003; Gallistel & Gelman, 1992; Jordan & Brannon, 2006; Piazza, 2010). In these studies, it has been demonstrated that there was no cost of comparing numerosities across versus within visual and auditory stimulus sets. They claimed that the comparison across presentation modality was not performed using modality-specific numerical representations but rather using the true abstract numerical representation system. Evidence for modality-independent numerical representation ability has also been claimed in infants (e.g., Jordan & Brannon, 2006; Kobayashi, Hiraki & Hasegawa, 2005) and animals (Jordan, Brannon, Logothetis & Ghazanfar, 2005).

It has, however, remained unclear whether these approximate numerical representations are truly modality-independent. Three primary reasons exist for doubting the modality-independence of the approximate numerical representation. First, some evidence has shown that there were significant differences in the performance of numerical judgments for visual, auditory, and tactile senses (e.g., Riggs, Ferrand, Lancelin, Fryziel, & Dumur, 2006; Lechelt, 1975; Philippia, van Erp, & Werkhoven, 2008). For example, in the rapid counting experiment, Lechelt (1975) compared adult performance in numerosity judgment of visual, auditory, and tactile stimuli and demonstrated that perceived numerosity differed among modalities. Philippi, van Erp, & Werkhoven (2008) demonstrated that the stimuli with a short interstimulus interval (ISI) are underestimated and the tendency is stronger for visual than for auditory stimuli. Second, it is known that the processing of temporal information is much more efficient in the auditory than in the visual modality (Penny, Gibbon, & Meck, 2000; Ivry, 2008). For example, in time related tasks such as duration discrimination and empty interval estimation, the performance in the auditory presentation is significantly better than that in the visual and the tactile presentations (e.g., Grondin, 2010). As it has suggested that the temporal information affects the numerical discrimination (Tokita & Ishiguchi, 2011), there is the possibility that numerical discrimination among modalities differed when the experimental conditions are rigorously controlled. Third, limitations may exist within experimental procedures of empirical studies that claimed modality-independence of numerical representation in terms of control of stimuli,

precision in measurement, and numbers of items tested. For example, Barth et al (2003) used a cross-modal comparison task and found that accuracy on these tasks was comparable to those on intramodal tasks, suggesting that non-numerical cues did not play a substantial role even in intramodal tasks. Numerical contrasts in their studies were, however, quite large such as Weber fraction of .50 or greater. With this level of measurement precision, the difference in the performance of each task could remain undetected. More to it, in infant and animal studies, the number of items tested was smaller than four. Because it remains unclear whether a system for representing small numbers of objects is distinct from that for representing larger numbers of objects, it is necessary to test whether the effects of sensory modality differ among a variety of numerosities.

In this study, we tested whether and how the numerical comparison of visual, auditory, and cross-modal presentation would differ under the adequate control of the concerns discussed above. We measured Weber fractions of discrimination task to assess the difference in the precision. Many studies have shown that both behavioral and neuronal tuning functions obey the Weber law (i.e., discriminability depends on the ratio of the numerical to be compared) over a broad range of numerosities (e.g., Burgess & Barlow, 1983; Nieder & Dehaene, 2009; Tokita & Ishiguchi, 2011; Whalen, Gallistel, & Gelman, 1999). We also measured a point of subjective equality (PSE) to test the accuracy of numerical comparison. Importantly, we involved rigid stimuli controls so that other properties such as stimuli duration and interval duration would not be confounded with the number of elements.

In Experiment 1, we compared the performance of numerical discrimination between the visual and the auditory presentation. In Experiment 2, we compared the performance of the visual, auditory, and cross-modal numerical comparison to examine how the numerical information in the different modality may integrate.

## Experiment 1

We examined the precision of approximate numerical comparison in two sensory modalities: visual and auditory. The schematic view of stimuli presentation is shown in Figure 1.

In a visual condition, elements in a set were consisted of sequences of flashes, while in an auditory condition, elements in a set were presented in a tone sequence. We employed two levels of standard event numbers (i.e., standard number), 10 and 20, to test whether and how precision across presentation conditions would differ among standard numbers. To examine the precision, we obtained Weber fractions that indicate the participant's variance of numerical comparison. In deriving the Weber fractions, we used the method of constant stimuli in which participants in each trial decided which stimuli—standard or comparison—had more events.

## Method

**Participants** Five participants participated in the experiment. All had normal or corrected-to-normal hearing and vision. All participants had no prior experience in numerical comparison tasks.

**Design** Two independent variables were examined in the experiment: the sensory modality (i.e., visual and auditory) and standard number (i.e., 10 and 20). The numbers in the comparison stimuli for the standard number of 10 and 20 were “8, 9, 11, 12” and “16, 18, 22, 24”, respectively. Trials in the visual and auditory conditions were separated and each constituted trial blocks. Two experimental conditions were presented among participants in a counterbalanced order. Trials in all the standard number sets were intermixed within a block. Each condition had 320 trials (40 repetitions  $\times$  4 comparison levels  $\times$  2 standard numbers), resulting in 640 trials in total. Each block had 64 trials, with 10 blocks in total. Participants performed three or four blocks in each experimental session, which took three days in total. Intermissions of approximately three minutes were given between blocks. Sequence of the trials was completely randomized within a block. Standard stimuli came first in half the trials and second in the remaining ones. Participants were given 16 practice trials before the actual experiment began.

**Stimuli** In the visual condition, two sequences of light gray dots appeared in a dark gray display region. Luminance of the dot was approximately 8 cd/m<sup>2</sup>. In the auditory condition, two sequences of tone were presented with the built-in-speaker of the desktop computer at the intensity of about 60 dB (Sound pressure level). Auditory stimuli were 700 Hz pure sinusoidal sounds generated by Macintosh's computer.

Figure 1: Schematic view of stimuli used in Experiment 1 and 2. The pair of events was sequentially presented in random orders.

In both conditions, we carefully controlled the stimulus duration and the inter-stimulus interval (ISI) so that the time for a sequence and presentation rate of stimuli would not be confounded with the number of elements. All element in a particular sequence had the same duration, but the durations varied from sequence to sequence between 33 to 50 ms. In half of the trials in a block, the average ISI was 125 ms in both standard and comparison sequences. In the remaining half, average ISI in the comparison sequences were carefully controlled so that average total interval for the standard sequence and that for the comparison sequence would be approximately equal. Thus, the number of events would be the only cue for numerical judgments. Many studies have provided evidence that the minimum ISI between two successive stimuli for correctly reporting their temporal order is about 40 ms and that this order threshold is invariant for auditory visual stimuli (e.g., Poppel, 1997; Kanabus, Szélag, & Poppel, 2002). Thus, sets of events in this experiment were perceived as successive independent of the sensory modality. To make the sequence aperiodic, we randomly added temporal jitter (−24, −17, −8, 0, 8, 17, or 24 ms) to each ISI so that the temporal rate would not constitute a rhythmic pattern.

Importantly, ISI were carefully determined so that the participants would not make judgments based on the verbal counting and/or temporal patterns. To make verbal counting impossible, the longest stimulus interval was set to be less than 250 ms, as previous studies have proved that participants could not rely on verbal or sub-verbal counting within that duration (e.g., Piazza, Mechelli, Price & Butterworth, 2006; Tokita & Ishiguchi, 2011).

**Measurements** The PSE and Weber fractions were measured using the method of constant stimuli. First, the number of events in comparison stimuli was plotted on the x axis and the proportion of “greater” response for each comparison stimulus was plotted on the y axis. The plotted data points constructed the psychometric function approximated by a cumulative Gaussian function, on which the difference threshold was obtained. This difference threshold was defined as the smallest amount of the element number change, for which a correct response rate of 75% was achieved. Weber fractions were obtained by dividing the difference thresholds by the standard numbers. The PSEs were obtained as the value of the location on the psychometric function at which the standard and comparative choice probabilities were equal to 50%. In this experiment, we obtained the standardized PSE, dividing the PSE by the standard number.

**Procedure** Participants sat in a darkened room at a distance of approximately 115 cm from the presentation screen. A numeric keypad was placed directly in front of the participants. The participants made responses by pressing the “1” or “3” key.

Each trial started with a red fixation cross for 400 ms followed by the first sequence. Pairs of sequences—standard and comparison sequences—were shown in

succession in random order. The two sequences were separated by a stimulus interval of 1100 ms.

The participant’s task was to choose which sequence, the first or second, contained more elements. Feedback with a short beep sound was given when participants made an incorrect choice. At the beginning of each session, the participants were explicitly instructed to attend to the number of elements presented and to discriminate on the basis of the numerical they felt, and not by verbal counting. They were also instructed to see the center of monitor in the auditory condition as well.

A Macintosh G4 computer was used to generate the display and the sound, and to record the data. Stimuli were presented on a color monitor at a refresh rate of 120 Hz (SONY Color Graphic Display Model GDM-F400).

Figure 2: Average psychometric functions for the each presentation condition (a) standard number of 10 and (b) standard number of 20.

Figure 3: The means of Weber fractions in the visual and the auditory conditions at standard number of 10 and 20. Error bars represent standard deviations.

## Results and discussion

Figure 2 shows the average psychometric functions for each standard number. Figure 3 shows the mean Weber fraction in each condition. The fits of data points to psychometric functions were generally good, and the Pearson moment correlation coefficient exceeded 0.9 in all cases with the exception of the visual condition at the standard number 10 and 20 for one participant. The data of the participant were excluded while those of the remaining participants were used for further analysis.

To test whether and how precision in numerical comparison differs between the visual and the auditory conditions, a 2 modality (visual and auditory)  $\times$  2 standard numbers (10 and 20) repeated measures analysis of variance (ANOVA) was conducted on individual Weber fractions. This yielded a significant main effect for presentation modality [ $F(1, 3) = 90.38, p < .01$ ]. Weber fractions in the auditory condition were significantly smaller than those in the visual condition, suggesting that the numerical judgment in auditory modality was more precise than that in visual modality. No significant effect of the standard numbers was observed [ $F(1, 3) = .48, p > .1$ ], suggesting that the precision of numerical judgment was not affected by the number of elements within the numerical range tested in this experiment.

## Experiment 2

We tested the precision of approximate numerical comparison in three presentation conditions (i.e., visual, auditory, and cross-format). Since no systematic difference was observed between the standard numbers, we only use one standard number 10 in this experiment. Stimuli presentations of the visual and the auditory conditions were the same as those in Experiment 1. In the cross-modal condition, elements in one set were presented in the visual

sequence and those in the other set were presented in the auditory sequence. To examine the precision, we obtained Weber fractions that indicate the participant's variance of numerical comparison. To test the accuracy of the numerical comparison, we derived the point of subjective equality.

## Method

**Participants.** Newly recruited five participants participated in the experiment. All participants had no prior experience in numerical comparison tasks. All had normal or corrected-to-normal hearing and vision.

**Design** We compared three presentation conditions: the visual, the auditory and the cross-modal condition. The cross-modal condition had two sub-conditions: the cross-modal condition 1 and the cross-modal condition 2. In cross-modal condition 1, standard stimuli were visual sequence and comparison stimuli were auditory sequence. In cross-modal condition 2, standard stimuli were auditory sequences and comparison stimuli were the visual sequences. The numbers in the comparison element for the standard number at 10 were "7, 8, 9, 11, 12, and 13".

Trials in the visual, auditory, and two cross-modal conditions were separated and each constituted trial blocks. Three experimental conditions were presented among participants in a pseudo-counterbalanced order. Each condition had 192 trials (32 repetitions  $\times$  6 comparison levels), resulting in 768 trials in total. Each block had 48 trials, with 16 blocks in total. Participants performed five to six blocks in each experimental session, which took three days in total. Intermissions of approximately three minutes were given between blocks. Sequence of the trials was completely randomized within a block. Standard stimuli came first in half the trials and second in the remaining ones. Participants were given 12 practice trials before the actual experiment began.

Figure 4: Average psychometric functions for the each presentation condition.

The stimuli, measurement, and procedures were the same as those in Experiment 1, with following exception. In the cross-modal condition, the auditory stimuli and the visual stimuli were shown in succession in random order.

## Results and discussion

Figure 4 shows the average psychometric functions for each condition. The fits of data points to psychometric functions were generally good, and the Pearson moment correlation coefficient exceeded 0.9 in all cases. Figure 5 shows the mean of Weber fractions and that of standardized PSEs of all participants. We averaged over Weber fractions for two cross-modal conditions for all participants and used the data for further analysis.

In order to test whether and how precision in numerical comparison differs between the visual, the auditory, the cross-modal conditions, a 3 condition repeated measures ANOVA was conducted on individual Weber fractions. There was a significant main effect for presentation modality [ $F(2, 4) = 9.43, p < .01$ ], and a Bonferroni post hoc analysis revealed that the Weber fractions in the visual and the cross-modal conditions were significantly larger than those in the auditory condition, indicating that precision in the visual and the cross-modal conditions was substantially worse than that in the auditory condition the same as the results in Experiment 1. The results suggested that the performance of the cross-modal trials would lie between that of the visual and auditory trials.

In order to test how cross-modal comparison affected the accuracy of numerosity comparison, we conducted a one-sample  $t$  test to compare the mean of the PSEs of the cross-modal condition 1 and that of the cross-modal condition 2 with the PSE of 0, respectively. The mean of PSEs in the cross-modal condition 1 was significantly larger than 0 [ $t(4) = 3.54, p < .05$ ] and the mean of PSEs in the cross-modal condition 2 was significantly smaller than 0 [ $t(4) = -5.43, p < .05$ ]. The results showed that the number of visual stimuli was overestimated relative to that of auditory stimuli in both cross-modal conditions.

## Discussion

We investigated whether and how precision in approximate numerical judgment between visual, auditory, and cross-modal presentations would differ. Our results demonstrated three significant findings. First, precision for numerical comparison of auditory sequence was significantly higher than that of visual sequence across two standard numbers. Second, precision in the visual and the cross-modal conditions was substantially worse than that in the auditory condition. Third, the number of visual elements was overestimated relative to that of auditory elements. Taken together, our results imply the existence of modality-specific processes in numerical comparison of the visual and auditory stimuli.

Our results are consistent with the previous studies that have shown the difference in counting precision across

modalities (e.g., Lechelt, 1975). Lower precision in the visual presentation is also consistent with the results of those studies. It is noteworthy that the similar effects were observed between the counting task and numerical comparison task.

What is the source of difference in the precision in numerical representation between visually and auditory presented stimuli, and how does the discrepancy in precision occur? In any modality, or cross-modal condition, stimuli need to be successively enumerated across time when the items of a set are presented sequentially. In this condition, the cardinal value of stimuli can be represented by the last numerical quantity. Common aspects of those numerical judgment is that they are time related irrespective to the sensory modality. In other time related tasks such as duration discrimination and empty interval estimation, it is known that the performance in the auditory presentation is significantly better than that in the visual and the tactile presentations. Thus, it is predicted that the temporal resolution may cause the superiority of auditory modality in numerical judgments. Further investigations are necessary to explore the possibility.

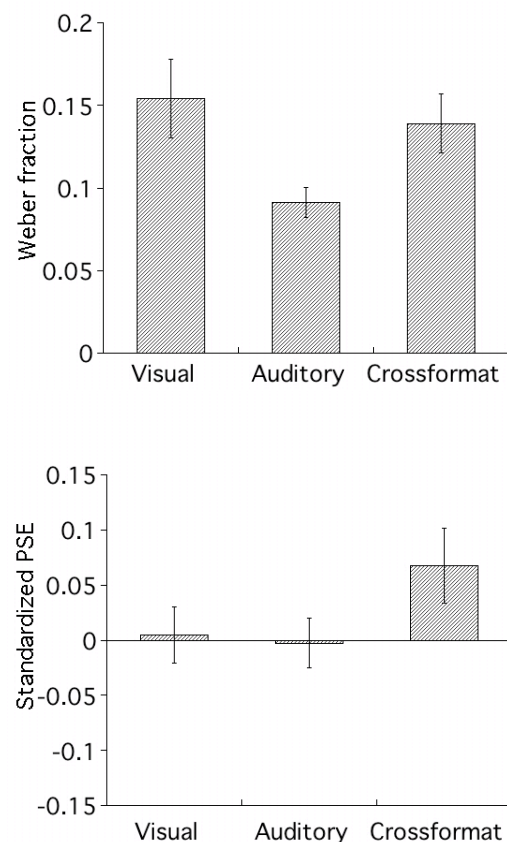

Figure 5: The means of Weber fractions and the means of PSEs of each modality condition. Error bars represent standard deviations.

As the performance of the cross-modal trials seemed to lie between that of the visual and auditory trials, it could be predicted that the convergent system could integrate the information from the auditory and visual numerical processing to form the higher abstract numerical presentations.

Another novel finding from this study is the overestimation of visual stimuli in the cross-modality comparison. Why did observer overestimate the number of visual stimuli relative to that of auditory stimuli? One possibility is that observers may overestimate the number of events with greater uncertainty (i.e., visual stimuli) in the decisional process. Another possibility is that the observers may perceive the events at the faster rate more numerous; since the time estimation for visual stimuli is shorter than the auditory stimuli, the visual stimuli appear with faster rate when they are presented at the identical rate. To test this possibility, we need to examine how human compare numerosities across modality in further investigation.

In conclusion, this study provided evidence for modality-specific processes in approximate numerical representation in human adults. Although many studies support the idea that human adults as well as infants and non-human animals share the modality-independent numerical system, it remains unknown how numerical information from the modality-specific system is combined at the judgment stage. Our findings imply that the process of approximate numerical representation is complex and involves multiple stages.

# Embodied Communication Practices in Instructive Interaction between Musicians

Jackson Tolins (jackson.tolins@colorado.edu)

Department of Linguistics, Hellems 290, 295 UCB

Boulder, CO 80302 USA

## Abstract

Musicians, in the discussion and teaching of their art, commonly make use of vocalizations in order to demonstrate a particular melody or musical phrase. In the present study, we consider the use of these vocalizations as part of embodied depictions, and the role that these embodied communication practices play in music instruction. Data drawn from video recordings of private lessons between a clarinetist and his instructor demonstrate that these enactments are used in order to (re-)represent the experience of both performing and listening. The music instructor makes use of these embodied depictions for a number of actions central to teaching the art, including assessment, direction, and displays of understanding. In considering body-based communicative practices as an instructive tool, we consider both simulation and social action based cognitive perspectives through application in the analysis of goal-oriented interaction.

**Keywords:** Instruction; Embodied Cognition; Non-lexical Speech; Social Actions; Gesture; Body; Music Education.

## Introduction

For musicians, the ability to talk to each other about what is essentially a non-linguistic domain (music) plays a vital role in the teaching, rehearsing, and performing of their art. The requirements of the structured activity of music instruction motivate the musicians to make frequent use of ‘nonsense’ syllables during interaction; for example ‘*it sounds really effective, but it sounds a little bit urrrllliiaa*’. These non-lexical vocalizations appear to be a crucial and commonly used resource, for both teacher and student, in music instruction, despite the large and well-established technical vocabulary available. From a traditional linguistic view, these vocalizations are semantically null, and cannot be used as arbitrary and conventional referencing symbols (Goodwin, Goodwin & Olsher 2002). Yet in the situated activity of the music lesson, much of the instruction is achieved through their use. How is this accomplished? Understood within a framework of embodied cognition, which emphasizes the role of modal representations (Barsalou 2008), these ‘nonsense’ syllables become much more; they represent a means of sharing direct perceptual experience, providing the participants of the interaction the ability to make use of the mental machinery involved in perception and simulation for the purposes of learning and development.

The purpose of the current paper is to demonstrate that the interactive goals of the lesson, namely the teaching and learning of music performance, are achieved by and motivate the use of these embodied vocalizations as perceptually parallel direct experiences of the music under discussion. Combined with gestures, body movements,

prosodic contours, and interaction with the physical environment, the nonsensical speech sounds depict the music under discussion. By taking the framework of embodied cognition, through which behavior is understood in relation to the perception- and action-based systems of the body (Barsalou, 2003; Barsalou, 2008), the vocalizations can be understood as a means of grounding the interactive goals of the lesson in direct experience.

## Embodied Cognition and Instruction

Theories of embodied cognition, which have been invoked in a wide range of fields, focus on the explaining cognitive phenomena through an understanding of agent-environment dynamics. In contrast to cognitivist and computational paradigms, embodied cognition replaces the study of amodal symbolic representation and processing with the study of mental simulations and situated action as the basis of cognition. They provide an especially appropriate foundation for the study of the instruction and education of a non-verbal art such as music. In many types of instructional settings, body-based communication techniques anchor complex ideas and increase comprehension (Iverson & Goldin-Meadow, 1998; Goldin-Meadow, Kim, & Singer, 1999). For a paradigm in which cognition is situated socially and cognitive work is off-loaded onto the environment (Wilson, 2002), the use of multimodal communication practices in an educational setting aides in establishing appropriate learning and problem-solving behaviors (Nathan, 2008). For example, both children who are instructed to manipulate physical objects while reading mathematical story problems, and those instructed to imagine the manipulation have higher gains in problem solving ability than their non-imagining counterparts (Glenberg, Jaworski, Rischal, & Levin, 2007).

The paradigm of embodied cognition has been applied successfully to the study of body-based and situated mathematics education (see e.g. Lakoff & Nuñez, 1997; Nuñez, Edwards, & Matos, 1999). These researchers have focused on the embodied conceptual system from which mathematical reasoning arises, as well as the role played by the situated social contexts in which learning occur. These studies demonstrate that difficult concepts in a domain such as mathematics can be explained, in a manner beneficial to improving curriculum, through an understanding of the relationship between our perceptual experiences and our conceptual structures.

Similar to math education, an instructive setting such as a music lesson provides researchers interested in grounded cognition theories a naturalistic source of data through which to study both embodied communicative practices and

the social actions achieved through their use. Music performance requires a number of physical, sequential, and emotive skills, the learning of which takes place over many years of instruction. The ethnographic study of music instruction offers a window into the role features of embodied cognition play in the development of non-verbal skills in the interaction between student and mentor.

## **Music and Language**

In the data collected for the present study, the musicians are clarinetists. For a clarinet, sound is produced by the vibration of a wooden reed fitted to the underside of the mouthpiece. In order to produce this vibration on the clarinet, the clarinetist forces air through the instrument with their breath in a manner that mirrors the production of speech. In a manner also similar to speech, the tongue is used in order to stop the vibration of the reed and thus produce gaps of various sizes between notes. By changing the way in which the tongue touches the reed, thereby stilling it, different styles and strengths of separation between notes can be achieved. The use of vocalizations in the embodied depictions can be viewed, then, as mimicking the sensations of performing on the clarinet, from the exhalation of air from the lungs to the use of the tongue at various locations and with various pressures throughout the mouth.

Recent research has also demonstrated that the online processing of music and language overlaps (Patel, 2008; Fedorenko, Patel, Casasanto, Winawer, & Gibson, 2009), indicating that listening to a vocalized depiction of music may be a more similar experience to directly listening to instrumental music than has been previously thought. This would allow for the musicians to substitute the direct experience of music played on the clarinet with the non-lexical speech sounds of the vocalizations.

## **Vocalizations as Overt Simulation**

Previous work on non-conventional, non-lexical speech sounds has focused almost exclusively in two arenas: non-linguistic quotes and the use of non-lexical speech sounds by aphasics. Goodwin et al (2002) demonstrated how an aphasic man was able to utilize nonsense syllables in order to communicate effectively with those around him. Similar work on the use of non-lexical vocalizations as a communicative tool for agrammatic aphasics has been done by Wilkinson and colleagues (2010), who showed that the use of embodied enactment is an effective interactional means to achieve social actions with limited lexical and grammatical resources. Non-linguistic quotations, on the other hand, ("the car went *vrrrm*"), are typically described in particular syntactic constructions in the literature (Hudson, 1985), commonly as non-linguistic demonstrations in which the speaker depicts, rather than describes, their referents (Clark & Gerrig, 1990).

Given the similarities between both experiencing and performing music and experiencing and performing speech sounds, it becomes possible for the musicians to take

advantage of this similarity for the rehearsal of their art. Indeed, many music teachers will recommend mental rehearsal through making use of any opportunity, such as a walk across campus, to mentally play through a piece. Research into the role of simulation and imagined actions in the planning and execution of actions, such as playing an instrument, has flourished within the last 20 years (Jeannerod, 2001; Barsalou 2010). These studies demonstrate that the covert rehearsal of actions takes on many of the same characteristics as overt action, including temporal characteristics key to music production and experience (Decety, Jeannerod, & Prablanc, 1989). Drawing on the cognitive processes involved in simulation of the voice and music perception can also increase memory of rhythmic patterns (Pich 2000).

The enactments considered below can be described as overt, shared simulation; simulation with an interactional purpose. The overlapping cognitive substrate activated for both the perception and mental imagery of speech sounds and music provides the means by which embodied depictions of music may be substituted for the direct experience, to the benefit of the goals of the situated activity.

## **Vocalizations as Social Actions**

In many activities where the focus of the interaction is a non-verbal domain, the use of embodied communication is invaluable. Particularly in an instructive environment, the embodied actions considered here play an integral role in the development of expertise (Lave & Wenger, 1991; Firth & Wagner, 2007; Melander & Sahlstrom, 2009). By analyzing how it is that the vocalizations are used to achieve the specific interactional goals of the music lesson, namely the development of the abilities of the student, we provide strong motivation for including the study of embodied communicative practices, as part of the study of education and instruction. In the data collected for this study three distinction actions were found that make use of the vocalizations; assessment, direction, and response. Most commonly, the embodied depictions are used as a means of conveying a critique of a previously experienced bit of music. The depictions are also frequently used as part of a directive, commanding the student to follow with a translation of the vocalization on his instrument. Lastly, the musicians use the vocalizations in response to a bit of talk in order to display an understanding of what has just been described.

## **Assessment**

Consider the non-lexical vocalization that occurs in the following transcript. In depicting the music played by the student, the instructor makes use of multimodal and embodied communication practices to highlight the quality he wishes to assess, emphasizing and exaggerating the particular feature in a way that allows the student to perceive the issue in the music as well. In this example, the depiction is quotative in that it indexes previously

performed music and gains its interactional meaning through this reference as part of the larger action of assessment and evaluation. Prior to the start of the transcript, the student has just finished performing a passage from Ned Rorem's *Poems by Sylvia Plath*, which ends with a run of short fast descending notes. The instructor, after giving a general positive assessment, highlights this run of notes and attempts to correct the way the student performs them. In the transcriptions, "I" is used to indicate lines spoken by the instructor, "S" for the student.

#### Transcript 1

- I: Now here  
**(points to sheet)**<sup>1</sup>  
 I: umm, make sure-  
 I: make sure that we hear  
 S: **(blows air through instrument)**  
 I: the fours. Right now it sounds really-  
 effective but it sounds a little bit  
 → *urrrllllliiaa*, youknowwhatI'msaying  
 → **(Hand across)**  
 S: mm hmm

The instructor uses the speech sounds that make up the vocalization to depict the lack of clarity between the notes. Unlike almost all other vocalizations found in the data, in which the nonsense syllables typically consist of an open consonant-vowel structure, one syllable for each note, the instructor uses a combination of vowels and liquid consonants to emphasize the slurred nature of his student's performance. This choice in speech sounds allows for an embodied experience of the indistinct quality that the instructor observed, and indeed the vocalization is the only source of the negative assessment in the interaction. The transition from the high vowels of [u] and [i] to the low vowel [a] can also be seen to mirror the downward motion of jaw required for the move from the high to low register of the clarinet. The manipulation of the voice, in combining speech sounds into nonsense syllables of particular pitch, loudness, and tempo, is a key feature of the depiction.

The action achieved by the use of the non-lexical vocalization is strengthened by the simultaneous use of gesture. While the instructor is making the '*urrrllllliiaa*' sound, he draws his hand across the space in front of him in a slowly downward moving motion before rotating his pinky finger upward in release (see figure 1). The smooth motion of the gesture mirrors the emphasized characteristic of the quotation, with both the vocal and spatial modalities working together to depict the nature of the music being critiqued (see also Bräm & Bräm 2004 for an analysis of gesture in music-oriented interactions). His whole body also takes part in the reenactment; while he maintains orientation towards the sheet music, his torso and shoulders sway and dip across to the left, following and emphasizing the motion

<sup>1</sup> **(Bold)** is used to represent physical actions co-occurring with the line directly preceding.

of his hands. Thus three different modalities - gesture, prosody, and speech - are being integrated in the embodied depiction.

Figure 1: Gesture co-articulated with vocalization. The black arrow represents the first movement path, the white arrow the second.

The distinct features of the vocalization as used for assessment are a) the location within an instructive action sequence, wherein the student's previous performance is the subject matter, and b) its use as a quotative device to both pinpoint the trouble source in the previous performance and to simultaneously provide a critique. Importantly the embodied depiction itself is the only spoken negative critique, contrasted with '*very effective*' as part of an explanation of '*make sure we hear the fours*'. The role of the student in listening to such a depiction is to take on the role of the expert, re-experiencing his performance from a less direct standpoint that allows him to critically assess the facets of his performance emphasized by the instructor's quotation, which he may then affirm, as he does in the last line of the transcript.

#### Direction

Beyond assessment, the embodied depictions are used to directly change a future performance of a piece of music. Rather than indexing a previous experience, these directives specify exactly how a subsequent portion of music should be played. These directives may be used for a number of reasons during instruction, including taking apart a difficult passage at a slower speed for familiarization, practicing various facets of the technical skills, and prescribing changes to performances, as the following transcript demonstrates. Here, the instructor presents a hypothetical performance in his vocalization, one that does not necessarily index any previous experience. Rather, by making use of the depiction, the teacher offers the student an overt simulation of the music and in doing so requests a like performance by the student. The student may then draw on this perceptual experience as the basis of his own playing, which he does directly subsequently in translating what he experienced in the vocalized simulation into playing the clarinet.

### Transcript 2

- I: Just play the F, make a little  
bit of a diminuendo and then think  
→ baadaadaaDAA  
→ I: leading! yapupuuPAA  
(student inhales and then plays)

These directives are used for a number of purposes in the activity of the lesson. As in the example above, they are used to make specific changes to the performance style of the student. They may also be in forming a deeper understanding of the music through directing the student to play in an unfamiliar manner, such as playing a passage with a particular subdivision of the rhythm, or at a reduced tempo. Through presenting the student with a new perspective on the music through the vocalization, and directing the student to then mimic the vocalization with his instrument, the instructor develops both the student's perceptual and action-based understanding of the music.

### Response

Finally, a third social action makes use of the embodied depictions in the instructional setting between the musicians. These act as responsive displays of understanding, and so work to depict what has just previously been described by the co-participant. In transcript (3) below, the student is attempting to describe the rhythmic breakdown of a passage. The instructor responds by vocalizing the passage under discussion as his interpretation of the student's description. By embodying the music in this manner, the instructor displays his understanding of his student's talk in a way that allows the student to provide uptake, which he does positively directly after the depiction.

### Transcript 3

- S: So right now I'm thinking more of a six  
(pause)  
S: I'm um going to-  
I: yaadaadaadaadaadaadaa  
(pause)  
S: yea. diyadadadada  
I: So you're going for the C  
S: Um, I mean, yea I think I'm trying to

Here, the instructor's vocalization enacts his understanding of his student's explanation, allowing the student to experience the music directly and confirm that the instructor has indeed understood what was meant. That the student then double-checks the accuracy of this vocalized depiction by repeating it to himself demonstrates the role these vocalizations play as perceptual anchors for their understanding of the music.

## Conclusion

The means by which the musicians make use of cognitive parallels between the perception of their voices and the perception of music is not easily understood in terms of a semantics based on amodal and symbolic processing. Instead, applying an embodied perspective we have demonstrated that the role of simulation in perception and action may be exploited by the interactants for the purposes of the situated activity of instruction. An ethnographic study of the use of embodied communicative practices in education drives home the need for a larger investigation into the role that embodied information processing plays in the development of procedural and technical skills. In the music lesson, the instructor makes use of the perceptually grounded comprehension of auditory phenomena, such as music and the voice, in order to commit a large number of distinct social actions essential to developing musicality on the part of the student. This includes the quotation of previously shared experiences to simultaneously point out the trouble spot and provide a critique, depicting novel musical expressions to be translated from voice to instrument, and displaying understanding of some bit of talk. In contrast to previous studies that focus on the role of embodied experience to develop abstract concepts, these few examples demonstrate that the instructor is able to manipulate the perceptual-experiential systems of simulation *in situ* to rapidly and accurately share perspectives that will lead to the development of his student. Music is but one of many non-verbal domains in the arts and other technical skills in which the study of embodied communication practices could lead to the development of improved education.

## Acknowledgments

I would like to thank Barbara Fox and the members of CU Language Project for many helpful conversations and comments, and the musicians for their willingness to participate.

## Abstract

Previous research has demonstrated a tight link between object perception and action: viewing an object primes the action needed to interact with it, while priming an action can affect the speed and accuracy with which we perceive the object. However, it is not yet known whether motor information can qualitatively change what object we actually perceive. We investigated this issue by having participants view or perform an action before viewing an ambiguous object. Results showed that viewing an action (a picture of a hand displaying a power or precision grasp) biased participants to interpret the ambiguous object as congruent with the action prime (Experiments 1 and 2). Conversely, performing an action (moving small or large balls from one tray to another) biased participants to interpret the object as incongruent with the motor action. Together, these results suggest viewing and performing actions can actually change what we see.

**Keywords:** Object perception; Action; Embodiment

## Background

Can our actions influence how we perceive the world and affect the very contents of our visual awareness? Though perception and action have traditionally been studied independently in the cognitive sciences, in our everyday experience of the world they are dynamically linked. For example, many of the objects we look at are also the objects we grasp and manipulate. More generally, our movements and actions in the environment alter what perceptual information we have access to, and these changes in perceptual stimulation consequently influence how we traverse our surroundings and what actions we choose to take. For reasons such as these, ecologically orientated psychologists have argued that we perceive the world in terms of how it affords action (Gibson, 1979).

In recent years, researchers have gathered evidence in support of this view, showing tight links between perception and action across a wide range of cognitive and behavioral tasks (e.g., Witt & Proffitt, 2005; Bhalla & Proffitt, 1999; Witt, Proffitt, & Epstein, 2004). Other researchers have examined the role that motor actions play in object perception (e.g., Borghi et al., 2007; Bub et al., 2008; Chao & Martin, 2000; Helbig, Graf, & Kiefer, 2006; Tucker & Ellis, 1998, 2001; Witt & Brockmole, in press; Witt, Kemmerer, Linkenauer, & Culham, 2010). For example, Tucker and Ellis conducted a series of studies to test whether people automatically generate a motor representation in response to the visual presentation of an object, even when there is no intention to act on the object (Tucker & Ellis, 1998; 2001). In one experiment,

participants made a left or right-handed button press to indicate whether an image of an object on the screen was upright or inverted. The objects were chosen to have a clear right or left-handed affordance (e.g., a frying pan with a handle oriented to the left affords a left-handed grasp). Participants responded faster and made fewer errors when their responding hand was congruent with the (task-irrelevant) affordance of the object on the screen.

Additional work has found that the relationship between motor actions and object perception is *functional* and not merely epiphenomenal. For example, Borghi et al. (2007) found that participants were faster to respond a picture of an object when it was preceded by a picture of a hand displaying an action that was congruent with the object. The authors concluded that visually priming an action facilitates object recognition (see also Helbig et al., 2006, Witt & Brockmole, in press). This suggests that preventing someone from engaging in an action should impair object recognition in a parallel fashion. Indeed, Witt et al. (2010) showed that participants were slower and less accurate when responding to a picture of a tool if the handle in the picture was oriented towards the participant's hand that was busy squeezing a rubber ball.

Taken together, these studies suggest that motor information can play a significant role in object perception by affecting the speed and accuracy with which we perceive an object. However, it is unclear just how deeply motor information can penetrate into our visual perception of objects. For instance, can viewing or performing a particular action *qualitatively* affect this perceptual process and change what object we actually see?

We investigated this possibility across three experiments. In Experiments 1 and 2, participants first viewed an image of a hand depicting a particular action (one of two specific grasp types). They then saw an image of an ambiguous object and had to indicate what they perceived it to be. Participants were biased to interpret the object as congruent with the action prime.

What cognitive mechanisms might underlie this effect? One possibility is that viewing the hand action prime led participants to imagine or simulate performing that action themselves (Parsons, 1987; Rizzolatti & Craighero, 2004). Then, when they viewed the ambiguous image, participants saw the object they were prepared to interact with because of this active motor state (Hommel et al., 2001). On this view, perceived events and planned actions share a common representational medium to the extent that they share common (abstract) features. Alternatively, this effect may

have simply been a result of purely visual or semantic priming due to the association between certain grasp types and certain objects.

To distinguish these possibilities, in Experiment 3 participants engaged in an actual manual motor action (moving small or large balls from one tray to another) while naming pictures displayed on a computer screen, including the ambiguous object used in Experiment 2. A visual priming account would predict that performing an action should have no effect on this task as long as participants cannot see their own hands as they engage in the action. A semantic priming account would predict that no matter how the action concept is activated (e.g. viewing an action, talking about an action, performing an action), the results should yield the same facilitation effect observed in Experiments 1-2. Conversely, the common coding approach would predict that performing an action should actually *interfere* with a participant's ability to perceive an action-congruent object, which will therefore lead them to perceive an action-*incongruent* object (Hommel et al., 2001). In this study, participants were actually biased to interpret the object as incongruent with the motor action they performed. This suggests that viewing and performing actions are supported by the same underlying representations.

## Experiment 1

Can viewing an action change what object we see?

### Methods

**Participants** 815 individuals were recruited to participate in this study through the amazon.com Mechanical Turk website in exchange for payment.

**Stimuli & Procedure** The stimuli for this experiment consisted of four photographs of hands and an ambiguous object line drawing created by the authors (Figure 1). The four hand photographs showed either left or right hands in either a power or precision grasp. Pilot testing suggested that the ambiguous object could be interpreted as an object that afforded a power grasp (*flashlight*) or as an object that afforded a precision grasp (*screw/bolt*). The drawing could also be interpreted as an object that afforded a right-handed functional grasp (e.g., the *flashlight* as oriented in Figure 1) or as an object that afforded a left-handed functional grasp (e.g., the *screw/bolt* as oriented in Figure 1).

**Figure 1.** In Experiment 1, participants viewed one of the four hand images on the left, and then viewed the ambiguous object on the right.

One of the four hand images was randomly selected for each participant and displayed on the screen for three seconds. Next, the ambiguous object drawing was displayed at 56% the size of the hand for three seconds. The left/right orientation of the drawing was counterbalanced across participants. After this, participants were asked to identify the object in the line drawing that they had just seen. They were then asked to identify whether the hand they had seen was a left or right hand. Finally, they were asked if they had any additional interpretation of the object and indicated whether they were left-handed, right-handed, or ambidextrous.

### Results

The data from 179 participants were removed from analysis because they failed to respond to the test questions appropriately (e.g., did not provide an interpretation of the ambiguous object), because they took the survey more than once, or because they responded incorrectly to the question of whether the hand prime they saw was a left or right hand. This last question was used as manipulation check to ensure that participants were looking at and paying attention to the experimental stimuli.

*Testing for effects of grasp type.* For the remaining 636 participants, we coded their initial ambiguous object interpretation as *congruent* if it matched the hand prime they saw (i.e., power grasp hand and flashlight interpretation or precision grasp hand and bolt/screw interpretation). Responses were coded as *incongruent* if they did not match the hand prime (i.e., power grasp hand and bolt/screw interpretation or precision grasp hand and flashlight interpretation). 19 participants came up with both interpretations for the ambiguous object and were therefore removed from further analysis.

Of the 617 participants in this final set of data, nearly 61% (N=374) gave *congruent* responses, while 39% (N=243) gave *incongruent* responses (Figure 2). A chi-square goodness of fit test revealed that this difference was highly significant,  $\chi^2 = 27.4, p < 0.0001$ .

**Figure 2.** Results from Experiment 1, showing proportion of congruent and incongruent object interpretations. Error bars represent the standard error of the proportion.

One possible explanation for these results is that our study design was transparent and therefore our participants simply

told us what they thought we wanted to hear. If our results were caused by this demand characteristic, then participants presumably perceived *both* interpretations for the ambiguous object and selected the interpretation they believed would make us happy. We tried to account for this possibility by asking participants if they had any additional interpretation of the object as one of our follow-up questions. In fact, 126 of our 617 participants provided additional interpretations of the object. Among the remaining 490 participants who only perceived one object interpretation, the results mirrored our previous analysis: nearly 61% (N=297) gave *congruent* responses, while 39% (N=193) gave *incongruent* responses. A chi-square goodness of fit test revealed that this difference was highly significant,  $\chi^2 = 21.7, p < 0.0001$ .

*Testing for effects of orientation.* We also asked whether the laterality of the action prime or participants' own handedness biased perception of the ambiguous object. To test these possibilities, participants' interpretations were coded as *leftward* if they saw the object whose handle (i.e., the head of the "bolt" or the barrel of the "flashlight") pointed to the left, and *rightward* if they saw the object whose handle pointed to the right. Neither the laterality of the action prime (51% congruent, N=249; 49% incongruent, N=241;  $\chi^2 = 0.1, p > 0.5$ ), nor the handedness of the participant (51% congruent, N=238; 49% incongruent, N=237;  $\chi^2 < 0.01, p > 0.5$ ), predicted whether subjects made a leftward or rightward interpretation of the object.

## Discussion

In this experiment we asked whether viewing an action would influence what participants saw when they looked at an ambiguous object. We found that when participants were primed with a hand displaying a power grasp they were more likely to interpret an ambiguous drawing as an object that required a power grasp (*flashlight*). Conversely, when they were primed with a hand displaying a precision grasp, they were more likely to interpret the drawing as an object that required a precision grasp (*screw/bolt*). These results remained even after we removed participants who provided multiple interpretations of the ambiguous object, which helps to rule out an explanation based on demand characteristics. These findings suggest that viewing an action can qualitatively affect our perception of an object.<sup>1</sup>

However, manual actions are complex, and grasp type is just one dimension out of many that might affect object

perception. In Experiment 1, we also tested whether priming an action with a right or left hand, irrespective of whether it displayed a power or precision grasp, would influence whether people perceived a leftward or rightward-facing object. We also reasoned that action simulations might be constrained by the idiosyncrasies of an individual's own motor system, so we tested whether the handedness of each participant, irrespective of the action prime, caused them to see a leftward or rightward-facing object. In our task, neither the laterality of the action prime nor the handedness of the participant affected what the ambiguous object appeared to be.

Why might the type of grasp displayed by a hand affect object perception, but not the laterality of the grasp or handedness of the participant? Perhaps some features of actions become privileged over others because they are more reliably associated with specific objects. Whether an object requires a power or precision grasp, for example, depends largely on the object's size, and for artifacts like flashlights and bolts, size is relatively constant across instances. The hand we use to grasp these objects, however, varies considerably depending on what we intend to do with the object and what else our hands are busy doing. By pitting various features of manual action against one another, we might have limited the likelihood that weaker effects of laterality and handedness would materialize. Exploring this possibility with objects that are ambiguous on one dimension only is the subject of future work.

It is also worth noting that the object we used in Experiment 1 was a *tool* under all possible interpretations, which might further limit our ability to generalize the effects of viewing actions to all graspable objects. Would the patterns we found in Experiment 1 with the flashlight/bolt image extend to graspable objects whose *primary* affordance is related to eating and not grasping (e.g., fruit)? Furthermore, the flashlight/bolt image remains an abstract, ambiguous, unrealistic line drawing. Would a photorealistic image in which the ambiguity of the object was less obvious show similar effects from viewing actions? To test these possibilities, we replicated this study in Experiment 2 using a photorealistic image of an object that could either be seen as an apple or a cherry.

## Experiment 2

In Experiment 1 we found that viewing an action influenced what participants saw when they looked at an ambiguous object. However, it remains unclear whether these results will generalize to more realistic-looking objects that are not in the tool category. To address this issue, we created a new ambiguous object, the photorealistic image depicted in Figure 3 that can be interpreted as an apple (power grasp affordance) or a cherry (precision grasp affordance). We then replicated Experiment 1 using this new object.

## Methods

<sup>1</sup> The results of Experiment 1 replicate a pilot version of this study reported at an earlier meeting of the Cognitive Science Society conference (Flusberg, Toskos Dils, & Boroditsky, 2010). Though the main effect in that study was nearly the same as in Experiment 1, the nature of the ambiguous object we used (a line drawing that could be perceived as a football or a nut) limited how we could interpret the results. First, this object elicited much more varied interpretations than the stimuli used in the present set of studies, suggesting that it may have been perceived as an extremely abstract figure rather than a concrete object. Second, a greater proportion of participants had multiple interpretations of the object than we see in the present study.

**Participants** 353 individuals were recruited to participate in this study through the amazon.com Mechanical Turk website in exchange for payment.

**Stimuli & Procedure** The stimuli and procedure for this experiment were identical to Experiment 1, with the exception of the ambiguous object, which was the cherry/apple picture depicted in Figure 3 presented at 29% the size of the hand.

**Figure 3.** The ambiguous object created for Experiment 2. It can be interpreted as an apple, which affords a power grasp, or a cherry, which affords a precision grasp.

## Results

The data from 22 participants were removed from analysis because they failed to respond to the test questions appropriately, because they took the survey more than once, or because they responded incorrectly to the question of whether the hand prime they saw was a left or right hand. For the remaining 335 participants, we coded their initial ambiguous object interpretation in the same way we did in Experiment 1. Four participants came up with both interpretations for the ambiguous object and were therefore removed from further analysis.

Of the 331 participants in this final set of data, 58% (N=192) gave *congruent* responses, while 42% (N=139) gave *incongruent* responses (Figure 4). A chi-square goodness of fit test revealed that this difference was highly significant,  $\chi^2 = 8.16$ ,  $p < 0.005$ . Once again, we used responses to our follow-up question to help rule out a demand characteristic account of these results. 110 participants provided additional interpretations of the object. Among the remaining 221 participants who only perceived one object interpretation, the results mirrored our previous analysis. Nearly 62% (N=136) gave *congruent* responses, while 38% (N=85) gave *incongruent* responses. A chi-square goodness of fit test revealed that this difference was highly significant,  $\chi^2 = 11.32$ ,  $p < 0.001$ . The pattern of results produced by the *cherry/apple* in Experiment 2 did not differ reliably from the pattern produced by the *flashlight/bolt* from Experiment 1,  $\chi^2 = 0.03$ ,  $p > 0.5$ .

## Discussion

The results of Experiment 2 replicated what we found in Experiment 1 using a photorealistic ambiguous object that was in a very different category from the tool image used in the previous study. Taken together, these experiments

demonstrate that viewing an action can qualitatively change how people perceive an object.

**Figure 4.** Results from Experiment 2, showing proportion of congruent and incongruent object interpretations. Error bars represent the standard error of the proportion.

What cognitive mechanisms might underlie this effect? One possibility is that the hand action prime led participants to simulate performing that action themselves (Parsons, 1987; Rizzolatti & Craighero, 2004). Then, when shown the ambiguous image, participants saw the object they were prepared to interact with because of this active motor state (Hommel et al., 2001). On this view, perceived events and planned actions share a common representational medium to the extent that they share common (abstract) features. Alternatively, this effect may have simply been a result of visual or semantic priming due to associations between grasp types and objects. Importantly, these accounts make three distinct predictions about how performing an action when participants cannot see their hands should affect object perception. A visual priming account would predict that performing an action should have no effect on this task as long as participants cannot see their own hands as they engage in the action. A semantic priming account would predict that no matter how the action concept is activated (e.g. viewing an action, talking about an action, performing an action), the results should yield the same facilitation effect observed in Experiments 1-2. Conversely, the common coding approach would predict that performing an action should actually *interfere* with a participant's ability to perceive an action-congruent object, which will therefore lead them to perceive an action-*incongruent* object (Hommel et al., 2001). Experiment 3 was designed to differentiate among these possibilities by having participants perform a manual motor action while they observed the ambiguous object used in Experiment 2.

## Experiment 3

Can performing an action change what you see in the same way that observing an action does?

## Methods

**Participants** 102 individuals were recruited to participate in this experiment from the Stanford community in exchange for course credit or five dollars.

**Stimuli & Procedure** When participants entered the lab, they were told they would be partaking in a study of multitasking. They were then seated at a desk and positioned with their head in a chin rest facing a computer screen (Apple iMac, 20" monitor). At this point they were given detailed instructions for how to proceed in the task.

The motor action participants performed consisted of picking up and moving balls located in a tray underneath the desk they were seated at (Figure 5). Participants picked up one ball in each hand from the lower tray and moved them simultaneously to the upper tray whenever they heard a beep coming from the computer. The apparatus was designed so that balls placed in the upper tray would fall back down into the lower tray. Importantly, with their heads in the chinrest, participants could not see this action as they performed it. Half of the participants were randomly assigned to pick up tennis balls, which require a power grasp action, while the remaining participants picked up small bouncy balls, which require a precision grasp action.

**Figure 5.** The laboratory setup used for Experiment 3. Half of participants moved bouncy balls in each hand (upper-right) while the remaining participants moved tennis balls in each hand (lower-right).

When the experiment began, the screen was black. A beep was played every 1.25 seconds, and each time it played participants engaged in the ball moving action. After 12.5 seconds, pictures started appearing on the screen one by one, each one remaining on the screen for 2 seconds, with an inter-stimulus interval of 500 milliseconds. While these pictures were appearing, the beeps kept playing at a rate of one every 1.25 seconds (twice per image).

Participants were instructed to name aloud the image on the screen as quickly as possible. There were 12 images in all, and the first 11 depicted objects or scenes that did not afford a particular manual grasp action (e.g., beach, house, etc.). The final image was the ambiguous cherry/apple

object used in Experiment 2. The pictures were presented in the same order for all participants.

## Results

The results from 2 participants were removed because they failed to complete the experimental task (i.e., they did not name every picture that appeared on the screen).

For the remaining 100 participants, we coded their response to the final picture (the ambiguous cherry/apple) as *congruent* if it matched the action they were performing (moving tennis balls and said apple, or moving bouncy balls and said cherry), and *incongruent* if it did not match the action they were performing (moving tennis balls and said cherry, or moving bouncy balls and said apple). 21 participants said both cherry and apple and were therefore removed from further analysis.

Of the 79 participants in this final set of data, 33% (N=26) gave *congruent* responses, while 67% (N=53) gave *incongruent* responses (Figure 6). A chi-square goodness of fit test revealed that this difference was highly significant,  $\chi^2 = 8.56, p < 0.005$ . This pattern differed reliably from the patterns observed in Experiment 1, ( $\chi^2 = 20.87, p < 0.0001$ ), and Experiment 2,  $\chi^2 = 18.06, p < 0.0001$ .

**Figure 6.** Results from Experiment 3, showing proportion of congruent and incongruent object interpretations. Error bars represent the standard error of the proportion.

## Discussion

In this experiment we asked whether performing an action would influence what participants saw when they looked at an ambiguous object. We found that when participants engaged in power grasp action (moving tennis balls in each hand), they were biased to perceive an ambiguous object that was *incongruent* with that action (i.e., a cherry, which affords a precision grasp). Similarly, when they engaged in precision grasp action (moving small bouncy balls in each hand), they were also biased to perceive an ambiguous object that was incongruent with that action (an apple, which affords a power grasp).

Therefore, it seems that performing an action can change what people see when they look at an ambiguous object, and the direction of the effect suggests that it arises from overlapping representations between perception and action. Indeed, as predicted by the common coding account (and not by visual or semantic priming mechanisms), the specific pattern of results in Experiment 3 shows the *opposite*

pattern from what we observed in Experiments 1 and 2 (when participants simply observed an action). In those experiments, viewing an action resulted in a *priming* effect, such that participants were biased to perceive an object that was congruent with the action they observed. In Experiment 3, on the other hand, performing an action resulted in an *interference* effect, such that participants were biased to perceive an object that was incongruent with the action they were engaged in.

However, there is one key difference between the experiments that may also have contributed to these divergent results. While participants in Experiments 1 and 2 only observed a single visual hand prime, participants in Experiment 3 engaged in a repetitive series of manual actions, moving balls from one tray to another 34 times. Behavioral repetition of this sort has been known to cause *adaptation* effects such that performance on a subsequent task is biased in the opposite direction of repeated behavior (e.g., Cattaneo et al., 2011). We are currently working on a new series of laboratory studies designed to tease apart the different possible mechanisms that may underlie the divergent patterns of results observed in these experiments.

### General Discussion

We began this paper by asking whether viewing or performing an action could qualitatively affect how people perceive an object. That is, does our current motor state change how we see the world?

In Experiments 1 and 2, participants first viewed an action hand prime and then viewed an ambiguous object. They were biased to perceive the object as congruent with the preceding hand image. When the hand prime displayed a power grasp, participants were more likely to see an object that afforded such a grasp, like a flashlight or an apple. When the hand prime displayed a precision grasp, participants were more likely to see a bolt or cherry, which afford the same grasp type. In Experiment 3, participants performed a manual motor action while they interpreted the ambiguous object. When they were picking up tennis balls, which afford a power grasp, they were more likely to see an object that afforded a precision grasp (i.e., cherry). Similarly, when they were picking up small bouncy balls, which afford a precision grasp, they were more likely to see an object that afforded a power grasp (i.e., apple).

These results demonstrate that viewing or performing an action can in fact qualitatively change what an object is perceived to be, and the pattern of results across experiments suggests that this shift is subserved by shared representations between perception and action.

### Acknowledgments

The authors would like to thank Laura Malkiewich for creating our cherple stimulus and help with earlier versions of these studies. We would also like to thank all members of the Cognition Lab. This research was supported by a McDonnell scholars grant & NSF BCS #1058119 to LB.

## Abstract

The present study examines the different ways in which language structure marks individuation and cue early attention in a novel noun generalization task. Results in the present study extends the Boundary Shift Hypothesis, suggesting that the linguistic boundary between individuals and nonindividuals influences the perceptual boundaries and the correlational patterns formed overtime between ontological kinds. The results provide a new perspective on the facilitative role of linguistic markers in category formations, rather than strictly in boundary formations. This demonstrates the potential degree of cognitive processing among different language learners and lends support towards a mechanistic explanation of the role of language in categorial formations.

**Keywords:** category learning, categorical structure, ontology, ontological boundaries, linguistic structure, individuation

## Introduction

Language is a symbol system that maps the world's categories. It allows people to efficiently shape their world through abstract representations. Words have long been viewed as a vital unit that allows one to shape abstract information to promote and refine clusters of information for representational use. Such examinations allow one to group information into arbitrary categories that assist in later retrieval (with less effort and less cost). Categories are essential in all general learning and have become a key device in allowing children (Katz, 1963) and adults (Goldstone, Lippa, & Shiffrin, 2001) to effectively make sense of their surrounding world. Previous research concerning ontological boundaries provided evidence that suggests linguistic cues available in one's environment enhances the way world categories are distinctively perceived. The present mechanistic proposal hypothesizes that if a language supports both boundaries, then the cluster of correlations between perceptual and linguistic cues available in such language should readily aid in honoring all ontological categories. The present research addresses this question by examining how the Vietnamese language may honor different ontological boundaries and, more importantly, category formation.

## Categorical Structure and Ontological Distinctions

There are three different types of ontological categories in the world: Animate, Inanimate (Discrete), and Substances.

Distinctions between these categories depend on the magnitude of individuation. In the Individuation Continuum described by Lucy (1992), individuation occurs when an entity is conceptualized as bounded and discrete. In this continuum, animates lie at one end (more individualized) and substances at the other end (less individualized) of a continuous spectrum, with inanimates comprising the middle (i.e., animates——inanimates——substances). The likelihood that a particular entity is conceptualized as an individual varies systematically across the continuum from animates to substances (Lucy, 1992).

Learning associations for categorization that ties labels and meanings together facilitates relational judgments to be transferred to novel stimuli (Lupyan, Rakison & McClelland, 2007). For instance, when different labels were provided among the same exemplars, discrete differences are highlighted between the stimuli that affect one's judgment to separate items into different categories (Lupyan, Rakison & McClelland, 2007). A traditional approach to this issue has asked whether language is simply a symbol system that maps to all the relevant categories found in the world. Another view is that language creates and shapes human cognition (Whorf, 1956). People can interpret the world quite differently if they come from different language backgrounds and such differences have significant effects on the level of cognitive processing among these language learners (Cook, 1977; Bent, 2006). Research on the Japanese and English language, for instance, posits the importance of linguistic cues as a vital factor that couples available perceptual cues in the environment to facilitate perceptual regularities in the world (Imai & Gentner, 1997; Yoshida & Smith, 2005).

**Individuation in English** In English, individuation is frequently demonstrated by the count/mass distinction. Count nouns are nouns that can take the plural form (e.g. cups, cats), usually denoted with an *-s* after the noun. Thus, count nouns are conceptualized as discrete entities that are bounded and individualized. Mass nouns, however, are not pluralized (e.g., milk, water), but instead take continuous quantifiers (e.g., some, much). Thus, mass nouns are conceptualized as continuous entities that are unbounded and massed. For example, "*My cats (count noun) drank some (continuous quantifier) milk (mass noun) from the*

bowl” would be more grammatically correct than “My *many cat drank milks from the bowl.*” Although nouns may take both count and mass forms (e.g., “Would you like *some muffins?*”), English generally treats animates and objects as individuals, while substances are treated as masses. The likelihood of treating an object as an individual, therefore, drops markedly between objects and substances in English (Soja, Carey & Spelke, 1991; Soja, 1992; Imai & Gentner, 1997; Yoshida & Smith, 2003). See Figure 1 for an illustration. Further, solidity proves to be an important factor that highlights the contrastive nature between substances among other objects (Colunga & Smith, 2000). The key point here is that the English language privileges substances as continuous masses.

Figure 1: Three mutually dependent layers: linguistic, conceptual, and perceptual organization of the Boundary Shift Hypothesis. Linguistic individuation marks descriptive linguistic functions (e.g., lexical semantics/animacy, classifiers) available in each language—that is, *-iru* and *-aru* Japanese distinctions for animates; *mass/count* English distinctions for substances. Conceptual distinctions indicates the ontological categories—animates, inanimates/objects, and substances. Perceptual cues indicate the typical features associated with each ontological category provided in the real world. Different ontological distinctions for each language (Japanese and English; Yoshida & Smith, 2003) and the predicted boundaries for Vietnamese are illustrated.

**Individuation in Japanese** Japanese lexical and syntactic devices relevant to individuation are different from those in English (Yoshida, 2001). Japanese nouns that refer to multiple entities are not necessarily pluralized (e.g., the same expression can mean the same thing—“*there was a dog*” and “*there were many dogs*”). A particular plural suffix *-tachi* is never used with inanimate nouns (and is optional with animate nouns). There are unique quantifiers for animates, but those used for objects and substances form an overlapping set. The Japanese language also have separate ‘exists/is located’ verbs for animates and inanimates (*-iru* and *-aru* respectively). Thus, the likelihood of treating an object as an individual drops markedly between animates and objects in Japanese. See Figure 1. The key point here is that the Japanese language privileges animates as individuals (Yoshida & Smith, 2003).

In both cases, this can be considered as the consequence of different correlational patterns among the types of linguistic cues available in each language. Recent studies have taken such measure by providing a mechanistic approach in exploring the role of language in category

formations through the Boundary Shift Hypothesis (e.g., Yoshida & Smith, 2003, 2005; Hidaka & Saiki, 2004).

### The Boundary Shift Hypothesis

A mechanistic approach towards the formation of categorical organizations could, perhaps, be explained by the Boundary Shift Hypothesis (Yoshida & Smith, 2003). As introduced by Yoshida & Smith (2003), “ontological partitions” individuates the boundaries through specification of categorical concepts among the three distinct psychological forms (i.e., different kinds of existence) that serve as a foundation for human category learning (i.e., animals/animates, object/inanimates, and substance). Each category has its own set of perceived characteristics and children are able to categorize novel objects based upon its perceptual traits (Landau, Smith & Jones, 1988). Based on previous studies, it has been suggested that when children are presented with an object with eyes and/or limbs and a novel name, they are likely to select different objects that have the same shape and texture, thereby strengthening a category based on animate features (Yoshida & Smith, 2003). However, children are likely to form categories based on the same shape when objects are solid, angular, and made-up of multiple parts (Yoshida & Smith, 2003). The Boundary Shift Hypothesis explains ontological partitions by advocating the view that the language one learns influences or shifts the boundaries of the ontological space of objects and substances (Yoshida & Smith, 2003). Namely, this view suggests that categorization may be due to the correlational structure presented in the world (Samuelson & Smith, 1999). The cluster of correlations between perceptual and linguistic cues relevant to individuation enhances the perceptual characteristics of individualized entities and support formation of ontological categories (Yoshida & Smith, 2003). See Figure 2 and 3 for an illustration. Correlations among these perceptual cues and category structure, then, are systematically generalized by each language and differ accordingly among different language systems (i.e., consequences of different correlational patterns).

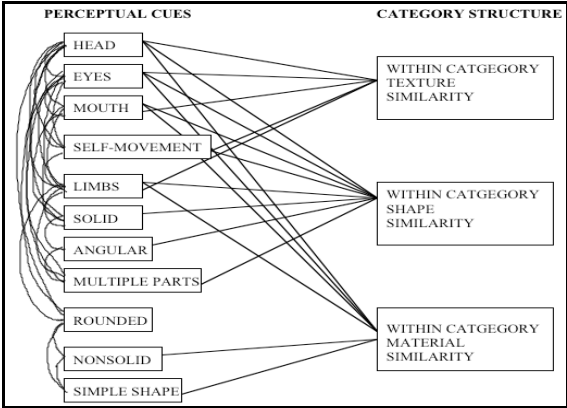

Figure 2: Illustration of associations between perceptual cues and category structure available in the world (Yoshida & Smith, 2003).

In this sense, language is viewed as a functional aspect that encompasses clusters of associations (i.e., weight of the correlations) that modifies the way we conceptualize categories. As demonstrated by Imai & Gentner (1993) and Yoshida & Smith (2003), psychological forms are conceptualized differently in English and Japanese. Thus, ontological categories are the products of learned correlations among the perceptual and linguistic cues.

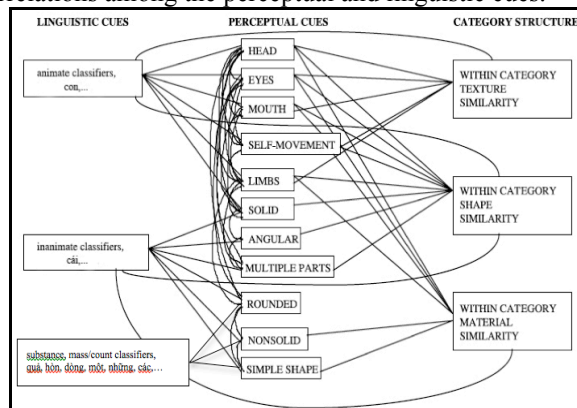

Figure 3: Associations among perceptual cues, category structure and linguistic cues available to learners of Vietnamese.

As a simple mapping system, language would honor the existing category structure and not influence category development. Thus, category development would be similar between children speaking different languages. The big question is, if language structure plays a vital role in shifting the boundaries between different ontological categories, would a language that have clear distinctions in representing different ontological structures demonstrate clear ontological partition (thus supporting the Boundary Shift Hypothesis)? All such theories predict that boundaries are formed from clusters of correlations; however, categorical knowledge is vast and may require more sophisticated ideas in explaining multiple categories. The purpose of the present study examines whether this type of boundary shifting (i.e., creating one boundary) is necessary for all children, or if children can reflect the reality of the three distinct categories. That is, the study explores the different ways in which language structure marks individuation by examining the Vietnamese language, which has implications in category formation through utilization of explicit classifiers to represent different ontological categories. If language does indeed influence category structure, we would expect to find a difference between the category formations of young children speaking different languages.

### Vietnamese Classifiers

Why Vietnamese? Vietnamese is a rich language that encompasses multitudes of explicit classifiers for speakers to conceptualize, classify, and describe spatial characteristics (shape, size, position) of objects in the surrounding world (Ly, 1999). Vietnamese classifiers are groups of nouns that have grammatical/syntax (Nguyen,

1963, 1975), semantic (Ly, 1999), and some implications in cognitive foundations (Lakoff, 1986; Friedrich, 1970). In the Vietnamese language, there are more than 40 different types of classifiers.

Vietnamese classifiers have two main functions: (1) singling out objects from different classes and, (2) help partition the world categories into various types (Ly, 1999). For example, in the sentence “con mèo” or “a cat” (CL+cat), the cat here is perceived as an individual animate object because of the classifier, whereas “cái ghế” or “a chair” (CL+chair) will be used to denote an individual inanimate object. In the Vietnamese language, the classifier “cái” is used most often for inanimate objects, while the classifier “con” indicates general animacy. Furthermore, classifiers describe explicitly the spatial characteristics of objects through the notion of salience and meaning. For instance, in English, the spherical feature is included in the meaning of the noun “ball” only implicitly. In Vietnamese, the same feature receives explicit expression by means of the classifier “quả/trái” (fruit/round-like), such as “quả/trái banh” or “a ball” (CL+ball).

Moreover, there are two types of classifiers: (1) Numerical (or non-descriptive) and (2) Descriptive. In numerical classifiers, an example would be “cái ghế” or “a chair” (CL+chair), which demonstrates that the classifier “cái” is indicating one chair. “Con”, however, may be used to describe inanimate and/or substances that are volitional in nature, such as “con sông” or “a river” (CL + river); “con dao” or “a knife” (CL + knife). When paired up with numerals, both classifiers may indicate count nouns. Without the use of “cái”/“con” preceding the noun, mass nouns would be implicated.

Additionally, there are certain distinctions for mass/count nouns in the Vietnamese language. For count nouns, singular forms are determined whether there is definite/limited size (e.g., “một cái bánh” or “a (one) piece of cake” numeral+CL+noun) or indefinite in size through the deletion of numerals (e.g., “cái bánh” or “piece of cake”; CL+noun). In a similar vein, plural count nouns are also dependent on definite/limited in size (e.g., “những cái bánh” or “some cake”; limited plural+CL+noun) and indefinite/maximal in size (e.g., “các cái bánh” or “every/all cake”; unlimited plural+CL+noun)—both of which can be viewed in parallel to the -s suffix that is added at the end of nouns in the English language. For mass or non-count nouns, however, it is not dependent on the size. Cao (1999) notes that mass nouns in Vietnamese are neutral to definiteness or non-definiteness. Where, in contrast, the zero article is used with a non-count noun (e.g., “bánh” or “cake” (zero or no CL+noun).

Given the richness of the descriptive language structure in Vietnamese, where would the Vietnamese language stand in regards to the Boundary Shift Hypothesis? That is, the linguistic boundary between individuals and nonindividuals perceptual boundaries between ontological kinds. Further, how do children come to understand the type of items or objects that are organized in different ways? Where does the

knowledge of different kinds of things emerge (i.e., animates, inanimates/objects, substances)? Japanese and English demonstrate homogenous differences in honoring two different ontological boundaries, is one or the other maximized or are both ontological distinctions present in the Vietnamese language? The present study hypothesizes that Vietnamese children should behave similarly to Japanese and English children—that is, the richness of the Vietnamese language should allow children to build distinct categorical formations for all ontological boundaries. See Figure 1. To test children’s knowledge of ontological categories, an adaptation of the Novel Noun Generalization (NNG) task was used (Soja, 1992). NNG tasks have been used to provide insight into children’s systematic expectations about how nouns map to distinct categories.

## Method

### Participants

Thirty monolingual Vietnamese participants with ages ranging from 23.85 to 33.22 months ( $M=29.59$ ,  $SD=2.91$ ) from Vietnam participated in the present study. Of the 30 participants, 20 completed the entire task and were therefore included in the analysis (attrition rate= 33.33%; 7 due to fussiness, 3 due to fatigue). Participants were recruited at a local preschool in Đồng Nai, Việt Nam. Prior to participation, all children were screened to ensure that Vietnamese was the only language they were regularly exposed to.

**Control.** Nine monolingual Japanese participants with ages ranging from 23.71 to 40.39 months ( $M=31.72$ ,  $SD=5.78$ ) from the USA (recently immigrated; temporary residents) participated in the present study for comparison results. Of the 9 participants, 8 participants completed the entire task (1 due to fussiness). Participants were recruited at a local Japanese daycare in Houston, TX. Primary caretakers were monolingual Japanese. Prior to participation, all children were screened on English and Japanese to ensure that Japanese was the only language they were regularly exposed to.

### Measurement Tools

A basic demographic questionnaire on language exposure and a parent checklist on productive vocabulary were used to ensure and control for homogeneity among the participants. To assess the children’s vocabulary, parents were asked to complete an adapted Vietnamese version of the MacArthur–Bates Communicative Development Inventories (MCDI; Fenson, Dale, Reznick, Bates, Hartung, Pethick, & Reilly, 1993). The Vietnamese version of the MCDI was developed by translating the American English (Fenson et al., 1993) and the Japanese MCDI (Ogura & Watamaki, 1997; see also Ogura, Yamashita, Murase, & Dale, 1993). Adult native speakers of Vietnamese translated and modified the documents. For the control group, the Japanese MCDI was used. The MCDI was used to control for vocabulary development among the participants.

### Procedure

Children sat at a comfortable distance from the computer screen in a quiet room at the preschool. A native Vietnamese experimenter sat next to the child and administered the task. A 5-minute break was implemented after the 27th trial (of 54 total trials) to reduce fatigue. Responses were recorded in-session by the experimenter.

### Task

The task was administered as a flash demonstration on a 15” HP laptop. There were a total of 54 trials consisting of 18 exemplars—6 animates, 6 inanimates, 6 substances—with 3 presentations each exemplar. Trials were presented in 6 blocks (i.e., 9 trials per block).

**Familiarization trials.** Children were presented with flash demonstrations of novel entities that were animate, inanimate, and substance. The objects were mixed and orders were randomized. All flash demonstrations began with the appearance of a novel object, followed by an animation of a hand acting upon the object.

Figure 4: Animate. Testing choices matched on Color+Texture (CO+TX), Shape+Color (SH+CO), and Shape+Texture (SH+TX) from left-to-right respectively.

Figure 5: Inanimate. Testing choices matched on SH, TX, and CO from left-to-right respectively.

Figure 6: Substance. Testing choices matched on CO, SH, and TX from left-to-right respectively.

For animates, the novel entity had animate characteristics such as blinking eyes and volitional mannerisms (i.e., moved out of the screen from the incoming hand). For inanimates, novel objects were depicted without animate

cues (i.e., angular, curvature, solid blocks) and demonstrated static mannerisms (i.e., incoming hand moved the object out of the screen). For substances, the non-solidity feature was illustrated by manipulations from the hand (i.e., incoming hand changed the shape of the substance). See Figure 4-6 for an example of the animate, inanimate, and substance stimuli used. During each flash demonstration, the experimenter would introduce a new novel label attached to each entity (e.g., “*Này là Phoom. Em thấy không? Đây là Phoom đó!*”/“*This is a Foom (novel label). See? This is a Foom (novel label)!*”). Instructions were given in a neutral manner (i.e., no classifiers were given) to avoid biasing the child’s response.

**Testing trials.** After each demonstration, children were shown three testing choices and were asked to identify which of the new testing choices presented is called by the same label (e.g., “*Em chỉ cho chị, nào là Phoom?*”/“*Can you point to the Foom (novel label)?*”). Again, questions were given in a neutral manner to avoid biasing the child’s response. For animates, testing choices were matched on Shape-Texture (SH+TX), Shape-Color (SH+CO), and Color-Texture (CO+TX). For inanimates and substances, testing choices were matched on Shape (SH), Texture (TX), and Color (CO). See Figure 4-6 for an example of the testing choices. According to Jones & Smith (2002), adult judgment indicates that the expected answer choice for animates should be organized by similarities based on SH+TX, SH for inanimates, and TX for substances.

## Results

Replicating previous results (Imai & Gentner, 1997; Yoshida & Smith, 2001, 2003), Japanese monolingual participants (control group) significantly chose feature matched on SH+TX ( $t(7)=2.986$ ,  $p<.05$ ) for animates, SH ( $t(7)=1.225$ ,  $p<.05$ ) for inanimates, and SH ( $t(7)=3.666$ ,  $p<.05$ ) for substances.

As predicted for the Vietnamese participants, results demonstrate that they honored all ontological distinctions—animates, inanimates, and substances—suggesting the role of language in category structure.

Figure 7: Proportion of expected choice for Animates matched on SH+TX, SH+CO, and CO+TX.

That is, Vietnamese participants significantly chose feature matched on SH+TX for animates, SH for inanimates, and TX for substances. Proportion of expected choices were performed against chance ( $p=.33$ ) using multiple t-tests. All expected choices were significantly above chance as illustrated by the star and dotted line (See Figure 7-9).

Specifically, in the *animate trials*, Vietnamese participants chose feature matched on SH+TX (expected) 53.89% of the time,  $t(19)=4.597$ ,  $p<.001$ , versus 28.61% for SH+CO match,  $t(19)=-.913$ ,  $p=.373$ , and 17.5% for CO+TX match,  $t(19)=-5.220$ ,  $p<.001$ . See Figure 7.

For the *inanimate trials*, Vietnamese participants chose feature matched on SH (expected) 56.38% of the time,  $t(19)=4.514$ ,  $p<.001$ , versus 20% for TX match,  $t(19)=-3.739$ ,  $p<.001$ , and 23.61% for CO match,  $t(19)=-2.021$ ,  $p=.058$ . See Figure 8.

Figure 8: Proportion of expected choice for Inanimates matched on SH, TX, and CO.

Finally, in the *substance trials*, Vietnamese participants chose feature matched on TX (expected) 48.89% of the time,  $t(19)=3.620$ ,  $p<.01$ , versus 26.67% for SH match,  $t(19)=-1.468$ ,  $p=.158$ , and 25% for CO match,  $t(19)=-2.010$ ,  $p=0.59$ . See Figure 9.

Figure 9: Proportion of expected choice for Substances matched on SH, TX, and CO.

## General Discussion

Results from the present study supports previous research (i.e., Boundary Shift Hypothesis) suggesting that the way in which children form categories depends largely on the language they are learning and the correlational patterns

they develop given the perceptual cues and regularities available in their environment. In particular, individuation among the perceptual boundaries between ontological kinds in the Vietnamese language is highly influenced by the availability and use of explicit classifiers within the language. Specifically, classifiers that highlight animates (i.e., *con*), inanimates (i.e., *cái*), and substance (i.e., numerical+CL inclusions for count nouns and deletion of classifiers for mass nouns) among the variety of classifiers help Vietnamese children to identify the discrete differences among different entities. Overtime, such regularities are produced to create clusters of correlations that allow children to form discrete ontological boundaries. This suggests that categorization is highly dependent on the structure of the language being learned, perceptual cues and regularities available in the environment, and the correlational pattern over time. The current results indicate that this phenomena is robust across tasks, regardless of task variations (Soja, Carey & Spelke, 1991; Soja, 1992; Imai & Gentner, 1997; Yoshida & Smith, 2003), among a variety of languages that foster distinct ontological boundaries. Therefore, we expect that English monolingual children should behave similarly from previous literature (Soja, Carey & Spelke, 1991; Yoshida & Smith, 2003). In sum, how children form categories may depend largely on the language they are learning and, in particular, on the way that language individuates kinds.

### Acknowledgments

Support for this research was provided in part by the National Institutes of Health grant (R01 HD058620), the Foundation for Child Development, and the University of Houston's Enhance and Advance Research (GEAR) program. We would like to extend our appreciation to the parents, teachers, and children who participated in the study. Special thanks are also due to Lauren Baker who created and designed the stimuli used in the present study.

## Abstract

Holistic processing has been identified as an expertise marker of face and object recognition. In contrast, the expertise marker of recognizing Chinese characters is reduced holistic processing (Hsiao & Cottrell, 2009), which is driven by Chinese writing experiences rather than reading ability (Tso, Au, & Hsiao, 2011). Here we investigate the developmental trend of holistic processing in Chinese character recognition and its relationship with reading and writing abilities by testing Chinese children who were learning Chinese at a public elementary school in Hong Kong on these abilities. We found that the holistic processing effect of Chinese characters in children was reduced as they reached higher grades; this reduction was driven by enhanced Chinese literacy rather than age. In addition, we found that writing performance predicts reading performance through reduced holistic processing as a mediator. We thus argue that writing hones analytic processing, which is essential for Chinese character recognition, and in turn facilitates learning to read in Chinese.

**Keywords:** Chinese character recognition, holistic processing, reading, writing, copying

## Introduction

Holistic processing (HP)—the ability to process separate features as a single whole unit—is an expertise marker for face and object recognition (see e.g., Bukach, Gauthier, & Tarr, 2006; Gauthier & Bukach, 2007; Richler, Wong, & Gauthier, 2011; though some argue that it is specific to faces, e.g., McKone, Kanwisher, & Duchaine, 2007). Chinese characters share many visual properties with faces. In contrast to words in most alphabetic languages that are linear in structure and consist of letter series of varying length, the Chinese writing system is logographic—The configuration of Chinese characters is more homogenous and square, and each character is a grapheme that represents a morpheme (Shu, 2003; Wong & Gauthier, 2006). The basic units of a Chinese character are strokes that combine to create more than a thousand different stroke patterns in the Chinese writing system; these stroke patterns form the characters (Hsiao & Shillock, 2006). A typical literate recognizes more than 3,000 individual Chinese characters regardless of variations in font (Hsiao & Cottrell, 2009). This is similar to face recognition in which faces are recognized individually regardless of variations in facial expressions (Hsiao & Cottrell, 2009; Wong & Gauthier, 2006). Despite the similarity between Chinese characters and faces, the expertise marker for Chinese character recognition is reduced HP (Hsiao & Cottrell, 2009).

Experienced Chinese readers employ less HP than novices in perceiving Chinese characters; this may be because Chinese readers are more sensitive to the internal constituent components of Chinese characters. They can readily ignore some configural information, such as exact distances between features, which are unimportant for character recognition (Ge, Wang, McGleery, & Lee, 2006). In contrast, these internal constituent components may not look easily separable to novices as they are less able to distinguish individual features and components in Chinese characters (Chen, Allport, & Marshall, 1996; Ho, Ng, & Ng, 2003; Hsiao & Cottrell, 2009). In addition, reduced holistic processing (i.e., analytic processing) of Chinese characters is enhanced by Chinese writing experiences (Tso, Au, & Hsiao, 2011). In Tso and colleagues' (2011) study, two groups of Chinese readers were tested: Chinese literates who could read and write (i.e., Writers), and Chinese literates who had limited writing exposure and thus had reading performance far better than writing performance (i.e., Limited-writers). Limited-writers had reading performance comparable to Writers', yet Limited-writers had far poorer performance than Writers in a dictation task (i.e., recall and write down a Chinese word when instructed). Writers perceived Chinese characters less holistically than Limited-writers—this between-group difference in HP could mainly be explained by dictation (writing) performance when the reading and copying variables were statistically controlled.

In Hong Kong, elementary schools do not explicitly place emphasis in its curriculum on teaching the Chinese character radicals (i.e., character components that consist of one or more identifiable stroke patterns); yet, children become more aware of the internal orthographic components in Chinese characters as they progress to higher grades (Ho et al., 2003). This may be explained by motor programming through extensive copying and writing as a requirement in Chinese lessons at school (Guan, Liu, Chan, Ye, & Perfetti, 2011; Tan, Spinks, Eden, Perfetti, & Siok, 2005). Reading performance is significantly predicted by copying ability (Chan, Ho, Tsang, Lee, & Chung, 2006; McBride-Chang, Chung, & Tong, 2011; Tan et al., 2005), as well as dictation performance (McBride-Chang et al., 2011; Tse, Kwan, & Ho, 2010). Writing experience may enhance reading ability because children may consolidate knowledge of graphomotor memory of character strokes as they copy the stroke patterns (Tan et al., 2005; Tse et al., 2010). Learning to write was experimentally shown to strengthen Chinese

character recognition (Guan et al., 2011). Neuroimaging studies also suggested that writing experience plays an important role in shaping reading-specialized neural representations (James & Atwood, 2009; Longcamp, Anton, Roth, & Velay, 2003; Siok, Perfetti, Jin, & Tan, 2004). All these results suggest a close relationship between sensory-motor integration development through writing practice and the development of reading skills, particularly for recognizing Chinese characters.

Although previous studies have suggested a close relationship between Chinese writing and reading performance in children, the underlying mechanism remains unclear (e.g., Guan et al., 2011; McBride-Chang et al., 2011)<sup>1</sup>. As reduction in HP of Chinese characters marks expert-level character recognition, here we hypothesize that writing experience enhances character recognition performance by modulating the perceptual system, allowing readers to identify Chinese characters more analytically (Tso et al., 2011). The modulating effect of writing experience on our perception of Chinese characters has never been studied before in Children who are learning to read and write Chinese characters. Here, we investigate whether children in upper grades perceived characters less holistically than children in lower grades in an elementary school where the Chinese language is taught. We also examine their Chinese reading and writing performance to see what can predict Children's reduced HP of Chinese characters. We predict that upper-grade children (who should have better Chinese literacy than lower-grade children) will process Chinese characters more analytically (i.e., less holistically) than children in lower grades. Because of the direct relationship writing experiences have with reduced HP (Tso et al., 2011), we hypothesize that children's reduction in HP can be predicted by writing performances across grades. Since writing performance also strongly correlates with reading abilities in Chinese (see e.g., Guan et al., 2011; McBride-Chang et al., 2011; Tan et al., 2005), we hypothesize that HP mediates between Chinese reading and writing abilities in children. More specifically, we predict that writing experience leads to reduced holistic processing in Chinese characters, which in turn enhances reading abilities in Chinese (Fig. 1)

Tso and colleagues (2011) also suggested that writing experience may facilitate reading Chinese characters in an unfamiliar font, as Limited-writers had difficulty reading words in the Feng font (a font that mimics handwriting and was unfamiliar to the participants) whereas this effect in Writers was minimal. Hence here we also examine the possible effect of enhanced Chinese writing proficiency on naming characters and words in familiar and unfamiliar fonts.

<sup>1</sup> Although some studies have proposed that writing enhances graphomotor memory of Chinese characters, which in turn facilitates reading (e.g., Tan et al., 2005; Tse et al., 2010). Yet, this hypothesis has not been statistically tested.

Fig. 1. Predicted mediation effect of reduced holistic processing between Chinese writing and reading performance.

## Methods

### Participants

56 first grade (mean age = 5.88 years, SE = .051), 73 third grade (mean age = 7.90, SE = .056), and 88 fifth grade (mean age = 9.89, SE = .047) Chinese children from an elementary in Hong Kong participated in our study. They were all Cantonese native-speaking and were all receiving regular Chinese language curriculum at school. All of them had normal or corrected-to-normal vision.

### Procedures

#### Test for holistic processing

To test for HP effects, we adopted procedures from Hsiao and Cottrell (2009). 160 pairs of medium to high frequency Chinese characters in Ming font were chosen; 80 pairs had a top-bottom configuration and 80 pairs had a left-right configuration<sup>2</sup> (Fig. 2). The frequency information of the Chinese characters was obtained from Ho and Kwan (2001). The top-down and left-right characters were matched in stroke number and frequency. In each trial, children were presented with two characters and instructed to attend to only half (either top or bottom for top-bottom characters, or left or right for left-right characters) of each character and judge whether they were the same or different. Forty pairs were presented in each of the four conditions (Fig. 3a): *same in congruent trials*, *different in congruent trials*, *same in incongruent trials*, and *different in incongruent trials*. The complete composite paradigm (Gauthier & Bukach, 2007) was adopted so that in congruent trials, the attended and irrelevant halves corresponded to the same response (i.e., both were the same or different) while in incongruent trials, the attended and irrelevant halves corresponded to different responses (e.g., the top halves were the same while the bottom halves were different). We adopted this paradigm to avoid response biases that may occur in the partial composite design in which the irrelevant halves would always be

Fig. 2. Examples of Chinese characters with left-right configuration (left) and top-bottom configuration (right).

different (see Gauthier & Bukach, 2007; Robbins & McKone, 2007; Richler, Cheung, & Gauthier, 2011).

<sup>2</sup> Both left-right and top-bottom are common Chinese character structures. Left-right is a more dominant structure than top-bottom in the Chinese lexicon.

In each trial, after 1,000 ms of central fixation, participants were cued with a symbol that indicated which half of each character they should attend to. The pair of characters was then presented, with one above and one below the initial fixation point, followed by a mask. During the 500ms presentation time, children looked at each character once and responded as quickly and accurately as possible by pressing corresponding buttons to judge if the character parts were the same or different (Fig 3b). Accuracy was collected. We measured participants' discrimination sensitivity  $A'$  as:

$$A' = 0.5 + \left[ \text{sign}(H - F) \frac{(H - F)^2 + |H - F|}{4 \max(H, F) - 4HF} \right]$$

$H$  and  $F$  are the hit rate and false alarm rate, respectively.  $A'$  is a bias-free nonparametric measure of sensitivity; we did not use  $d'$  because response biases may affect its measurement when assumptions of normality and homogeneity of variance are not met (Stanislaw & Todorov, 1999). The  $A'$  difference between incongruent and congruent trials (i.e., Holistic  $A'$ ) measures HP—a more positive value marks a stronger HP effect.

Fig. 3. Illustration of stimulus pairs in the complete composite paradigm and trial sequences (for top-bottom characters). In (a), the attended components are shaded in red. In (b), a 1,000 ms central fixation cross precedes each trial, followed by a cue either below or above the cross to indication which half (top or bottom) of the characters participants should attend to in the following display.

#### Tests for reading and writing performance:

Four tests were administered: 1. Character naming task, 2. Word naming task, 3. Character copying task, and 4. Word dictation task. Tasks 1 and 2 assessed participant's reading ability, while Tasks 3 and 4 assessed their copying and word recalling/writing ability respectively.

#### Reading tests:

##### 1. Character naming task:

Children were presented with 60 Chinese characters one at a time. Half of the stimuli were presented in Ming font (a commonly used font type; Fig. 4a) and the other half were presented in Feng font (an unfamiliar font type that simulates handwriting; Fig. 4b). They were instructed to read aloud the characters as quickly and as accurately as possible. The characters were arranged from high to low frequency (frequency information for primary students was obtained from Leung & Lee, 2001). The trials stopped after 5 consecutive errors made. Each trial started with a central fixation cross for 500ms, followed by the character presentation. The screen turned blank after a child had responded and the experimenter pressed a button to record the accuracy and to start the next trial. Their response time was measured as the time difference between the stimulus onset and the onset of the pronunciation, detected by a microphone.

##### 2. Word naming task:

Children read aloud 30 two-character words arranged from high to low frequency (frequency information for primary students was obtained from Leung & Lee, 2001) as quickly and accurately as possible. Half of the stimuli were presented in Ming font and the other half were presented in Feng font. The procedure was the same as that of the character naming task. The response time was measured as the time difference between the stimulus onset and the onset of the pronunciation of the first character.

Fig. 4. Examples of a Chinese character in Ming font (a) and Feng font (b).

#### Writing tests:

##### 3. Character copying task:

Children copied 30 characters (10 real characters, 10 pseudo-characters, and 10 Korean characters) as quickly and as accurately as possible. The Chinese characters were randomly selected from the characters used in task 1. The pseudo-characters were orthographically legal but non-sense characters. Each trial started with a central fixation cross for 500 ms, followed by the character presentation. Each time, after a child had copied a character, the experimenter pressed a button immediately and the screen turned blank to start the next trial. Their response time was recorded.

##### 4. Word dictation task:

Children wrote down 30 two-character words (the same words used in task 2) as quickly and as accurately as possible when they heard each word said in a female voice presented by a computer. Two-character words were used instead of characters to reduce ambiguity due to the many homophonic characters in the Chinese lexicon. Each trial started with the words "Get ready" on the screen for 500 ms. After hearing the word, participants pressed corresponding buttons to

indicate whether they could recall the word or not, before they started writing. After they finished writing, the experimenter pressed a button to indicate accuracy and to reveal the next word. Accuracy rate was recorded.

These experiments were all conducted using E-prime v2.0 (Psychology Software Tools, Pittsburgh, PA).

## Results

Repeated-measures ANOVA was used to investigate HP effects (congruency: congruent vs. incongruent trials x grade: Grade 1 vs. Grade 3 vs. Grade 5). We found a significant effect of grade ( $F(2, 213) = 25.090, p < 0.001$ ), a significant effect of congruency ( $F(1, 213) = 268.319, p < 0.001$ ), and an interaction between congruency and grade ( $F(1, 213) = 11.376, p < 0.001$ ). The main effect of congruency suggests that across grades, children process Chinese characters holistically. While the main effect of grade showed that the performance level increased with grade, the interaction between grade and congruency suggests that children processed Chinese characters with varying levels of congruency effect across grades (Fig. 5).

Fig. 5. A' of congruent and incongruent trials for first, third and fifth graders in the holistic processing task (\* $p < 0.05$ ; \*\* $p < 0.01$ ; \*\*\* $p < 0.001$ ).

Pairwise post-hoc t-tests showed that A' in congruent trials was larger than in incongruent trials in first ( $t(55) = 12.01, p < .001$ ), third ( $t(72) = 7.838, p < .001$ ) and fifth graders ( $t(86) = 8.439, p < .001$ ). In congruent trials, first graders had a smaller A' than third ( $t(127) = 3.226, p < .01$ ) and fifth graders ( $t(141) = 4.576, p < .001$ ) while third and fifth graders did not differ statistically in A' ( $t(158) = .994, n.s.$ ). In incongruent trials, first graders had a smaller A' than third ( $t(127) = 3.991, p < .001$ ) and fifth graders ( $t(141) = 7.878, p < .001$ ), and third graders had a smaller A' than fifth graders ( $t(158) = 2.450, p < .05$ ). We also conducted pairwise post-hoc t-tests on the A' difference between incongruent and

congruent trials (i.e., Holistic A') between children in the 3 grades. We found that first graders had a larger Holistic A' than third graders ( $t(127) = 2.334, p < .05$ ) and fifth graders ( $t(141) = 5.401, p < .001$ ), while third graders had a larger Holistic A' than fifth graders ( $t(158) = 2.230, p < .05$ ). These results suggest that HP of Chinese characters in children was reduced as they reached higher grades (see Fig. 5).

## Chinese proficiency tests

Pearson's correlation regression analysis showed a positive correlation between grade and character-naming accuracy ( $r^2 = .602, p < .001$ ), word-naming accuracy ( $r^2 = .512, p < .001$ ) and dictation accuracy ( $r^2 = .707, p < .001$ ); and a negative correlation between grade and character-naming response time ( $r^2 = .269, p < .001$ ), word-naming response time ( $r^2 = .347, p < .001$ ) and character-copying response time ( $r^2 = .620, p < .001$ ). These results suggest that children had better Chinese reading and writing proficiency as they reached higher grades.

## Font familiarity effect on character and word naming

Repeated-measures ANOVA (font: Ming vs. Feng x grade) was used for the analysis on character-naming response time. We found a main effect of font ( $F(1,181) = 16.9, p < .001$ ) and a main effect of grade ( $F(2,181) = 37.01, p < .001$ ), but no interaction effect was found between font and grade ( $F(2,181) = .348, n.s.$ ).

For word-naming response time, we found a main effect of font ( $F(1,177) = 17.1, p < .001$ ) and a main effect of grade ( $F(2,177) = 59.6, p < .001$ ). We also found an interaction

<sup>1</sup>  $p < 0.1$  \* $p < 0.05$  \*\* $p < 0.01$  \*\*\* $p < 0.001$

effect between font and grade ( $F(2,177) = 3.894, p < .05$ ). We then performed pairwise post-hoc t-tests on the response time difference between Ming font words and Feng font words among children in the 3 grades. We found that first graders had a larger font effect in response time than third graders ( $t(109) = 1.941, p = .055$ ) and fifth graders ( $t(117) = 2.192, p < .05$ ) while third and fifth graders did not differ statistically ( $t(128) = .135, n.s.$ ). These results suggest that word-naming performances depended greatly on font familiarity in lower grades than in upper grades. This font-grade interaction was not found in character-naming.

#### Hierarchical Regression Analysis

We investigated how HP could be uniquely predicted by literacy level by partialing out the variance due to age. As summarized in Table 2, HP was predicted uniquely by reading and writing performance and vice versa. The variance of HP can be significantly explained by reading and dictation performances, but not copying performance, when partialing out the variance due to age.

#### Mediation Analysis

We conducted a mediation analysis to test the mediation effect of HP between dictation accuracy and word naming accuracy<sup>3</sup>. Regression analysis revealed that Holistic A' predicted word naming accuracy ( $\beta = -.265, p < .01$ ). A Sobel mediation test showed that Holistic A' significantly mediated the relationship between dictation accuracy and word naming accuracy ( $z = 2.403, p < .05$ ). The mediator effect of Holistic A' was partial as the direct effect of dictation accuracy and word naming accuracy remained statistically significant,  $\beta = .635, p < .001$  (Fig. 6).

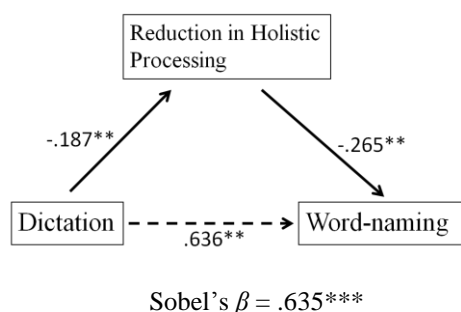

Fig 6. Partial mediation effect of reduced holistic processing on dictation and word naming performances (\* $p < 0.05$ ; \*\* $p < 0.01$ ; \*\*\* $p < 0.001$ ).

### **Discussion**

Our study showed that children in upper grades processed Chinese characters less holistically than children in lower grades. Further analyses showed that this effect could not be solely accounted for by age. Consistent with Hsiao and Cottrell's (2009) findings, better Chinese reading and writing proficiency strongly predicted reduced HP. Because

elementary schools in Hong Kong do not explicitly teach children Chinese character radicals (Ho et al., 2003), their reduction in HP in upper grades is more likely the result of enhanced Chinese literacy.

Previous studies had reported a close relationship between Chinese writing and reading performance. Yet, the underlying mechanism remained unclear (e.g., Guan et al., 2011; McBride-Chang et al., 2011; Tan et al., 2005; Tse et al., 2010). In our study, the mediation analysis suggests that HP is a significant mediator of dictation accuracy and word naming accuracy (Fig. 6). This result is consistent with our hypothesis that the HP effect in Chinese character recognition is predicted by writing performance (i.e., the ability to recall and write down Chinese characters), and in turn predicts word reading performance (Fig. 1). Perhaps writing experience enhances the ability to analyze the orthographic structures and components of Chinese characters in children, which leads to reduced HP (i.e., more analytic) as suggested in Tso and colleagues' (2011) study. Consistent with previous findings that suggest our sensorimotor learning influences our perception (He et al., 2003; James & Atwood, 2009; Longcamp et al., 2003), we show how writing performance can be associated with reduced HP in Chinese character recognition. In addition, we show that this change in the perception of Chinese characters (reduced HP) can in turn modulate reading performance. This study is also the first to report on the developmental trajectory of HP of Chinese characters in children.

Our results also revealed that children were better at recognizing Chinese characters and words in a familiar font (Ming) than in an unfamiliar font (Feng); this effect of font familiarity was more prominent in first graders than third and fifth graders. ANCOVA analysis showed that the group difference in the font familiarity effect became insignificant when dictation accuracy was set as a covariate ( $F(2,172) = 1.84, n.s.$ ). This suggests that writing experience, measured as the ability to recall and write characters here, facilitates reading words in an unfamiliar font (Tso et al., 2011). Further investigation, however, is needed to see whether this effect is due to a particular dimension or general improvement in literacy.

As future work, we will obtain information of HP of Chinese characters from non-Chinese speaking children that do not receive the local Chinese curriculum as a control group. We speculate that the pattern of their holistic processing of Chinese characters will not drop as much as Chinese-learning children as they do not learn to write Chinese explicitly.

In conclusion, our study provides an information processing account of the relationship between writing and reading ability in Chinese children. We show that children learning to read and write Chinese characters processed Chinese characters with reduced HP as they reached upper grades; this reduction in HP may be facilitated by writing experience and may in turn enhance word reading ability.

<sup>3</sup> This mediation pathway with word-naming accuracy as the first and dictation accuracy as the final step was not significant.

## Abstract

We studied action perception and the role of visual form and visual motion kinematics of the observed agent using a stimulus set of human and humanoid robot actions and electroencephalogram (EEG). Participants viewed 2s. videos of three agents (Human, Android, Robot) performing recognizable actions: Human had biological form and motion, Android had biological form and non-biological motion, and Robot had non-biological form and non-biological motion. Early in processing (P200), Robot was distinguished from the other agents, likely due to low-level visual properties of the stimuli. We found a right temporal N170, which was most pronounced for Human, indicating possible modulation of this face- and body-sensitive ERP component by biological motion. There was a centro-parietal negativity (N300) that was most pronounced for Robot, and a later one (N400) for Human and Android. In the same time period (N300), Android was distinguished in the frontal channels from the other agents. A late positivity (P600) distinguished Human, again in frontal channels. These results highlight differential spatiotemporal cortical patterns during action perception depending on the viewed agent's form and motion kinematics.

**Keywords:** action perception; body perception; biological motion; social robotics; artificial agents; neuroimaging; EEG, ERP; uncanny valley

## Introduction

Successfully perceiving and understanding others' body movements is of biological significance, from hunting prey and avoiding predators, to communication and social interaction. The functional properties of the

neural systems that support action and body movement perception is currently an active research area in cognitive science and neuroscience.

Artificial agents such as robots can perform recognizable body movements, but can have varying degrees of biological appearance (form) and motion. As such, they provide us with an opportunity to study the specificity of neural responses to the seen agent's form and motion (as well as mismatches between the two). A prominent idea in action perception is *simulation theory*, whereby others' actions are understood via an internal sensorimotor simulation of the seen action in our own body representations (Barsalou, 2009). Supporting this, neural activity for action perception shows modulation by the degree of similarity between the observed action or actor, and the observers' own body (Buccino et al., 2004; Calvo-Merino, Grezes, Glaser, Passingham, & Haggard, 2006; Rizzolatti & Craighero, 2004). In terms of artificial agents such as robots, one might thus predict that increasing human-likeness engages simulation mechanisms more effectively.

On the other hand, human resemblance is not necessarily always a positive feature in artificial agent design. According to the *uncanny valley theory*, as an agent is made more human-like, the reaction to it becomes more and more positive and empathetic, until a point is reached at which the agent becomes oddly repulsive (Mori, 1970), an effect well-known in robotics and animation. Despite anecdotal evidence, there is little scientific data to characterize the uncanny valley (MacDorman & Ishiguro, 2006; Saygin,

Chaminade, Ishiguro, Driver, & Frith, 2011; Steckenfinger & Ghazanfar, 2009).

Previous studies on the perception of actions of humanoid robots have not found consistent results for or against simulation theory (Chaminade & Cheng, 2009). In a recent fMRI study, a more complex relationship between neural responses and the human-likeness of the observed agent was observed (including potential neural signals related to the uncanny valley), suggesting that focusing on simulation theory may be too narrow (Saygin, Chaminade, & Ishiguro, 2010). Furthermore, the specific role of biological appearance or biological motion in action processing have not been sufficiently explored in previous work, but is an area of interest in both social robotics and cognitive neuroscience (Chaminade, Hodgins, & Kawato, 2007; Kanda, Miyashita, Osada, Haikawa, & Ishiguro, 2008; Saygin, Chaminade, Urgen, & Ishiguro, 2011).

Although fMRI studies have identified the brain areas that are involved in action observation, much less is known about temporal aspects of body movement processing (Hirai, Fukushima, & Hiraki, 2003; Jokisch, Daum, Suchan, & Troje, 2005; Krakowski et al., 2011; Press, Cook, Blakemore, & Kilner, 2011). Since action processing is a naturally temporally unfolding event, it is important to further study its neural dynamics.

In the present study, we manipulated the form and the motion of the observed agent and recorded neural activity in the human brain using high-density electroencephalography (EEG), which allows us to investigate neurophysiological processes on a millisecond time scale. We used a unique stimulus set of well-matched human and humanoid robot actions (Saygin, Chaminade, Urgen et al., 2011). The stimuli consisted of videos of three agents: Human, Android, and Robot (Figure 1). Human had biological form and motion, Android had biological form and non-biological motion, and Robot had non-biological form and non-biological motion. The latter two were actually the same robot videotaped in two different appearances, but with identical kinematics. Another dimension of the stimuli was the congruence in the form and movement kinematics of the agents. Whereas Human and Robot had congruence in their form and movement kinematics (both being biological or non-biological, respectively), Android had incongruence in its form and movement kinematics as it had a biological appearance but non-biological movement kinematics.

Our goal is to study the temporal dynamics of action perception and its modulation by the seen agent's form and motion in relation to current theories in the field. Neural signals that may index simulation process would be expected to show some specificity to the Human condition. If the simulation process is driven primarily by appearance, responses to the Android are expected to be similar to the Human. If on the other

hand, biological motion is important for engaging simulation, Android responses are instead expected to show the same pattern as the Robot. As for the uncanny valley theory, we would expect neural responses for the Android to be distinct from the other conditions. Of course, the simulation theory and the uncanny valley theory are not mutually exclusive, and there may be evidence for both, possibly at different brain regions and in different time periods.

## Methods

### Participants

Twelve adults participated in the study. Participants were recruited from the student community at the University of California, San Diego (3 females, mean age: 24.4). All participants were right-handed, had normal or corrected-to-normal vision and no history of neurological disorders. Participants were either paid \$8 per hour or received course credit for their participation. They were informed about the nature of the study and signed consent forms in accordance with the UCSD Human Research Protections Program.

### Stimuli and Procedure

The experimental stimuli consisted of 2-second videos of three agents performing recognizable actions: A Human, an Android, and a Robot (Figure 1).

Biological Motion	No	No	Yes
Biological Appearance	No	Yes	Yes
Congruent Motion and Appearance	Yes	No	Yes

Figure 1. Still frames from a drinking action for Robot, Android and Human agents and the experimental features of interest (form and motion).

The Android was Repliee Q2 (Ishiguro, 2006), and the Robot condition was the same robot in a modified appearance (Saygin, Chaminade, Ishiguro et al., 2011). We recorded EEG as participants watched video clips of the 3 agents carrying out five different upper body actions (drinking, picking an object, hand waving, talking, nudging). The experiment consisted of 15 blocks of 60 trials with equal number of videos of each agent.

The stimuli were displayed on a 22' Samsung monitor at 60 Hz. In order to prevent an augmented visual evoked potential at the beginning of the movie

onset that might occlude subtle effects between conditions, we displayed two consecutive gray screens (700-1000 ms and 500-700 ms, respectively) before each video clip. In order to minimize eye movement artifacts, subjects were instructed to fixate a fixation cross at the center of the screen. In order to control for subjects' attention throughout the experiment, every random 6-10 trials, a comprehension question was displayed (e.g., Drinking? Yes/No) and subjects responded with a bimanual key press.

### EEG Recordings and Analysis

EEG was recorded at 512 Hz from 64 ActiveTwo Ag/AgCl electrodes (Biosemi, Inc.) following the International 10-10 system. The electrode-offset level was kept below 25  $\mu$ V. Four additional electrodes were placed above and below the right eye, and lateral to the eyes to monitor oculomotor activity. The data were analyzed with MATLAB and the freely available EEGLAB toolbox (Delorme & Makeig, 2004). Data was high-pass filtered at 1 Hz, low-pass filtered at 50 Hz, and re-referenced to average mastoids. Atypical epochs of electromyographic activity were removed from further analysis by semiautomated epoch rejection procedures as implemented in EEGLAB. In order to discard eye-related artifacts, the data were decomposed by extended infomax ICA using binica as implemented in EEGLAB. The data were epoched time-locked to the onset of the video clips ranging from 200 ms preceding onset to 2000 ms after onset. Data was explored both qualitatively and quantitatively. Grand Average Event-related potentials (ERP) were computed using the BrainVision Analyzer 2 software package (BrainVision, Inc.). For display purposes, ERPs were low-pass filtered at 25 Hz.

Scalp topographies for the different conditions were generated. We identified specific channels and time periods for statistical analysis. For an unbiased analysis of differences between conditions, temporal regions of interest were determined from the mean grand average ERP activity across all conditions by visual inspection of all channels. The specific time window for each component was chosen to be the narrowest time window that was common to all channels that featured the respective component. This led to the selection of six time windows: 75-150 ms, 155-205 ms, 210-260 ms, 270-370 ms, 430-540 ms and 630-800 ms from stimulus onset. Not all channels had visible components in the ERP plots, but the temporal regions were chosen to be inclusive of all possible components of interest. Within each time window, we applied paired t-tests to compare individual mean amplitudes between conditions (Robot, Android, Human). The rationale of applying paired t-tests instead of ANOVA was because the former provide a test of our experimental hypotheses without considering

irrelevant comparisons. Since our design was not a full 2x2 factorial design with form and motion (lacking the non-biological form and biological motion condition) the main effect/interaction structure of a conventional ANOVA does not correspond to the experimental comparisons of interest (the effect of form, of motion, and of congruence of form and motion). Four of the analysed time windows showed the following 5 ERP components that significantly differed between experimental conditions: An occipital P200 (155-205 ms), a central temporal N170 (155-205 ms), a centroparietal and frontal N300 (270-370 ms), a frontal N400 (430-540 ms), as well as a central and frontal P600 (630-800 ms). Where we presented data from selected channels, these were chosen as representative channels among those in the same region (as evident in the scalp distributions in Figure 2) for distinguishing one of the agents (Human, Android or Robot), thus showing the modulation of the respective component by form, motion, or congruence of form and motion. The reported p-values have been corrected for multiple comparisons unless stated otherwise (at alpha level 0.05).

### Results

EEG scalp topographies of the three conditions differed both spatially and temporally. Early on, the processing

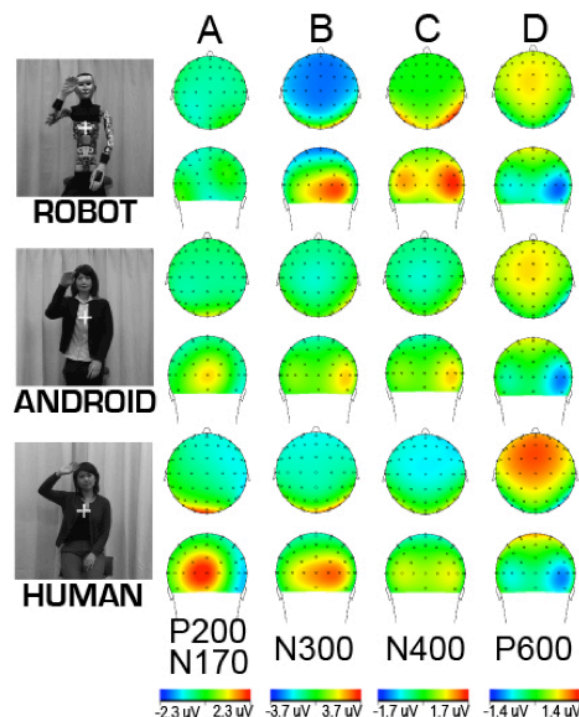

Figure 2. Scalp topographies corresponding to A) 155-205 ms (P200/N170), B) 270-370 ms (N300), C) 430-540 ms (N400), D) 630-800 ms (P600).

of Robot was distinguished from Human and Android, with an increased positivity across occipital regions for

the latter two agent conditions (Fig. 2A). Then, Robot was distinguished from Human and Android with a stronger negativity across frontal, central, and centro-parietal areas (Fig. 2B). Later, Robot was again distinguished from the other two agents with an increased positivity in centro-parietal regions, and Human was distinguished in the frontal regions (Fig. 2C). In a later stage, Human was distinguished with a stronger positivity in frontal regions (Fig. 2D).

The ERPs were then quantitatively compared across conditions to explore the role of biological form and biological action processing. Figure 3 shows ERP plots from representative channels in which the component of interest showed statistically significant amplitude modulations across conditions.

In the time window between 155-205 ms, we observed an occipital positivity (P200) that was stronger for Human and Android as compared to Robot ( $p < 0.05$ ). Although Human elicited an increased P200 than Android, Human and Android did not differ significantly, indicating a form-based modulation of this component (Fig. 3, Iz). The same time window also showed an N170 in right centro-temporal channel T8, which showed a motion-sensitive amplitude modulation (Fig. 3, T8): Here, Human (featuring biological motion) elicited increased negative amplitude compared to Android and Robot ( $p < 0.05$  and  $p < 0.01$ , respectively); the latter conditions did not differ significantly.

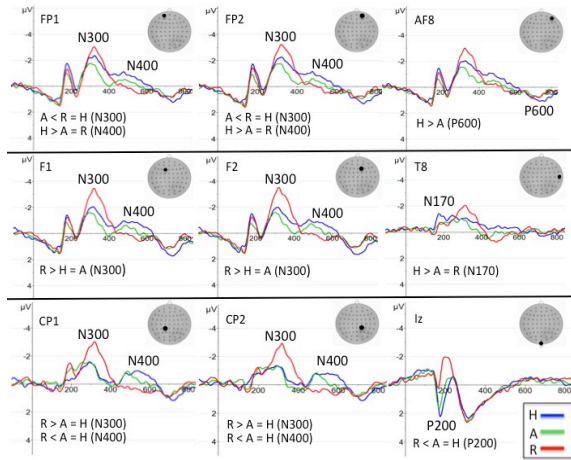

Figure 3. ERP Plots for selected channels depicting the condition effects for each component. (A: Android, H: Human, R: Robot)

Between 270 ms and 370 ms, there was a centro-parietal and frontal N300 (Fig. 3, CP1, CP2, F1, F2, Fp1, Fp2). Robot elicited a more pronounced negativity compared to Human and Android in frontal and centro-parietal channels bilaterally (Fig. 3 CP1:  $p < 0.01$ ; CP2:  $p < 0.01$ , F1:  $p < 0.01$ ; F2:  $p < 0.01$ ), indicating form-sensitive modulation. The N300 amplitudes of Human and Android did not differ. The same time window

showed less pronounced negativity for Android compared to Human and Robot in the most anterior-frontal channels bilaterally, possibly indicating a modulation by the (in)congruence of form and motion (Fig. 3, Fp1:  $p < 0.001$ ; Fp2:  $p < 0.05$ ). The responses for Human and Robot did not differ.

Between 430 ms and 540 ms, we observed a comparable negative amplitude in centro-parietal channels for Human and Android, which was absent for the Robot condition (Fig. 3 CP1, CP2), resulting in significant differences (Fig. 3 CP1 and CP2:  $p < 0.05$ ). In the same time window, in frontal channels, Human elicited an increased negativity compared to Android and Robot (Fig 3. Fp1:  $p < 0.05$ ; Fp2:  $p < 0.01$ ).

Finally, between 630 ms and 800 ms, we observed a late positivity peaking in frontal channels, which was increased for Human vs. Android (Fig. 3 AF8:  $p < 0.01$ ). The responses for Android and Robot did not differ in this time interval.

## Discussion

We investigated the temporal characteristics of neural activity during the perception of actions using a unique stimulus set of well-matched human and humanoid robot actions to manipulate the visual form and visual motion kinematics of the observed agent as we recorded electrical brain potentials (EEG). We found that neural activity during action perception is modulated differentially by the appearance and motion of the agent being observed, allowing us to observe the unfolding of perceptual and cognitive processes during action perception.

### P200

We found that an early stage of visual processing of the actions between 155-205 ms showed a form-sensitive modulation, where Robot (non-biological appearance) was distinguished from the other two agents (biological appearance, Figure 3 Iz). This is consistent with previous research on the P200 component, which is generally associated with early visual processing and is known to be sensitive to physical properties of visual stimuli (Luck & Hillyard, 1994). Since Robot had a distinct appearance from Human and Android, including low-level differences such as higher contrast and spatial frequencies, we interpret this effect as indicative of early perceptual differences, sensitive to the visual appearance of the agent being observed.

### N170

The early negative component N170, especially in the right hemisphere, has been associated with face and body processing in previous ERP research (de Gelder et al., 2010). In our study, the agents had different levels of anthropomorphism in their faces and bodies (i.e. biological vs. non-biological both in form and motion).

The Robot had a mechanical looking face with no movement, the Android and Human had similar facial appearance, but the Human face also featured biological motion (even though the actions used here did not feature prominent facial expressions and were upper body movements). We found that the amplitude of the N170 was modulated by the anthropomorphism of the agent, as manifested by a larger N170 for Human compared to the other agents. Since previous work on the N170 used static faces and bodies, our result may indicate that dynamic (biological) facial/bodily motion also elicits the N170. Another possibility is that the amplitude of the N170 might be differentially modulated depending on the presence of a context, as in our case the face was perceived together with the body during the performance of an action, whereas in previous work, still faces and bodies were shown as stimuli. As such, our results offer possible new studies to understand the functional significance of the N170 component.

### **N300/N400 complex**

The N300/N400 complex with an anterior distribution has been associated with the mapping of visual input onto representations in semantic memory (Sitnikova, Holcomb, Kiyonaga, & Kuperberg, 2008). The increased centro-parietal negativity that we found for the robot condition in the 270-370 ms time interval (Figure 3, CP1 and CP2) over anterior regions may reflect a difficulty in mapping visual input onto existing semantic representations, since robots are currently not very familiar, certainly not in the context of actions such as those in our stimuli (e.g., drinking from a cup). If this interpretation is correct, we can also deduce this process being driven primarily by the form of the agent, for if motion was a factor, the Android were equally, if not more difficult to match to semantic memory. There was also a significant effect in the same time range in frontal channels, where Android differed from the other two agents (Figure 3, Fp1, Fp2). Given the Android represents a mismatch between form and motion being potentially linked to the uncanny valley phenomenon (Ishiguro, 2006; Saygin, Chaminade, Ishiguro et al., 2011), this could be a potential component to explore in future studies on the uncanny valley, or on congruence of form and motion more generally.

### **P600 (late positivity)**

In previous work, a late positivity or P600 has mostly been studied in the domain of language and is most commonly associated with syntactic processing (Friederici, 2004). Few studies have interpreted the P600 in other domains (Sitnikova et al., 2008). In our data (Figure 3, AF8), we found that this component was elicited most strongly by the Human condition. This can lead us new avenues of research to understand the

functional significance of the ERP components observed in action perception.

### **Implications for Action Processing**

Although action processing has been an active area of study in cognitive neuroscience, most work to date has used fMRI rather than electrophysiology. More specifically, a number of studies have focused on the perception of human and robot agents with fMRI, with inconsistent support for the simulation theory (Saygin, Chaminade, Ishiguro et al., 2011). Here, we add new ERP results to this literature, providing information about the role of humanoid form and humanoid motion during the course of action perception.

The stimuli used here were previously utilized in an fMRI repetition-suppression study in which brain activity did not show evidence for form-based or motion-based simulation per se, but instead was most significantly affected by form-motion incongruence (Saygin, Chaminade, Ishiguro et al., 2011). Here, with a more time-resolved method, we found distinct stages of processing during which neural responses differed based on both the form and the motion of the seen agent. These effects were likely lost due to the temporal insensitivity of fMRI, highlighting the importance of using multiple, complementary techniques.

A well-known face-sensitive component, the N170, was elicited by our stimuli. Previous work on this ERP signature of face processing has used static face stimuli, as opposed to movies including the body as we did here. Our data suggest new possible ways in which the N170 can be modulated. Specifically we hypothesize that either biological motion of the face and/or the context provided by the body are modulators of the N170.

Our data did not reveal patterns of activity that can be linked straightforwardly to simulation theory. There was some selectivity for the Human (for whom simulation theory would predict differential effects, whether driven by form or motion) for the frontal N400 and P600, but there is little prior literature on actions for these components, and no link to sensorimotor simulation that we are aware of. The uncanny valley theory also cannot account for all of the patterns in our data, although the frontal N300 response could be interpreted as biomarker for the uncanny valley. These components should be viewed as possible indices related to each theory, to be tested in new studies.

Overall, in this first ERP study of action perception with human and humanoid agents, we highlight the complexity of action processing that can be revealed using more time-resolved methods. We found distinct neural signatures of the viewed agent's form and motion in different time periods, both early (perceptual) and late (cognitive) in processing. These results do not globally fit into either simulation or uncanny valley frameworks, although a focus on specific components

such as the N170 and N300/400 in upcoming studies might help better understand the mechanisms of action perception and its neural basis. Work on neural dynamics of action processing can not only shed light on the cognitive neuroscience of action perception, but also to inform the burgeoning field of social robotics (Saygin, Chaminade, Urgen et al., 2011).

## Acknowledgements

This research was supported by the Kavli Institute for Brain and Mind (APS), California Institute of Telecommunications and Information Technology (Calit2) (BAU, APS), NSF (SBE-0542013, Temporal Dynamics of Learning Center), and ONR (MURI Award # N00014-10-1-0072, HP). The authors would like to thank Marta Kutas, Arthur Vigil, members of the Intelligent Robotics Laboratory (Osaka University) for the creation of the stimuli, and Joe Snider (Poizner Lab) for his help in the experimental setup.

## Abstract

Only a few attempts have so far been made at exploring the process of metaphor production, although a large number of studies have addressed metaphor comprehension. Therefore, in this paper, we address the problem of how people generate metaphors or identify an apt vehicle for a given topic of metaphors. Specifically, we examine how the process and product of metaphor production differ between two discourse goals of metaphor, namely an explanatory purpose (e.g., to clarify) and a literary purpose (e.g., to aesthetically pleasing). Experiment 1 analysed the metaphors (or vehicles) generated in the metaphor production task, and demonstrated that people identified more prototypical exemplars of the property attributed to the topic as a vehicle for explanatory metaphors than for literary metaphors. In addition, it was found that explanatory metaphors were more apt and conventional, and had high topic-vehicle similarity than literary metaphors, while literary metaphors were more familiar and imageable than explanatory metaphors. Experiment 2 used a priming paradigm to assess the online availability of prototypical and less prototypical members of the topic property during metaphor production. The result was that both prototypical and less prototypical members were activated in producing literary metaphors, while neither members were activated in the production of explanatory metaphors. These findings indicate that the process of metaphor production is affected by discourse goals of metaphor, and suggest that only prototypical members of the category are rapidly searched for a vehicle during the production of explanatory metaphors, while both prototypical and less prototypical members are searched to generate literary metaphors.

**Keywords:** Metaphor production; Discourse goal; Priming

## Introduction

Metaphor has been a main topic of research in cognitive science, because metaphorical expressions are frequently observed in our everyday use of language. Hence, a large number of studies have been made on how people comprehend metaphors (e.g., Bowdle & Gentner, 2005; Gibbs, 2008; Glucksberg, 2001; Utsumi, 2011). In contrast, only a few studies have addressed the process of metaphor production (for a notable exception, see, for example, Chiappe & Chiappe, 2007; Katz, 1989). This paucity of research on metaphor production is especially problematic, given that by its very nature a metaphor is an intentional, linguistic device employed to convey ideas that might be otherwise inexpressible. To ameliorate this situation, in this paper, we empirically explore the process of metaphor production.

Previous studies on metaphor production analysed the products of metaphor production (i.e., metaphorical expressions produced) in terms of the qualitative dimensions of metaphors and/or individual differences. Concerning the qualitative dimensions of metaphor products, Fainsilber and Ortony (1987) demonstrated that descriptions of emotional states

contained more metaphorical language than did descriptions of actions. Katz (1989) examined the properties of metaphor vehicles by asking participants to choose, from a set of alternatives, a vehicle that completes a given sentence frame (e.g., Chemistry is the \_\_\_\_\_ of science) as comprehensible and apt metaphors. The result was that participants were likely to choose the vehicles that were moderately distant from the topic and referred to concrete domains. Concerning individual differences, it was demonstrated that the quantity and quality of metaphor products were affected by individual differences such as writing experience (experienced or novice) (Williams-Whitney, Mio, & Whitney, 1992), reasoning and imagery ability (Katz, 1989), gender (male or female) (Hussey & Katz, 2006), and working memory capacity (Chiappe & Chiappe, 2007). For example, Chiappe and Chiappe (2007) demonstrated that people with high working memory capacity produced more apt metaphors than did low capacity individuals.

Although shedding light on the specific aspects of metaphor production, these studies did not address one important aspect of metaphor production, namely *discourse goals of metaphor*. Because metaphors (and other figurative language) are intentionally used to accomplish certain communication goals (Roberts & Kreuz, 1994), it is obviously crucial to explore the effects of discourse goals on the process of metaphor production. Discourse goals that are accomplished by the use of metaphorical expressions can be classified broadly into two classes: explanatory and literary purposes (Steen, 1994; Utsumi, 2005). These two goals are quite different and sometimes incompatible with each other; explanatory metaphors are used to clarify certain properties of the topic, while literary metaphors are used to evoke an aesthetically pleasing feeling by enriching the meanings conveyed by the metaphors. It naturally follows that discourse goals are likely to affect the process of generating metaphors, or more specifically choosing the vehicles of metaphors. This paper aims at examining how the process and product of metaphor production differ between these two discourse goals.

In metaphor production, people often have in mind a topic that they want to express and some properties that they intend to attribute to the topic. They must identify an appropriate or apt vehicle to convey the intended meaning (i.e., the information that the topic has the property). Hence, metaphor production essentially involves the process of searching for or retrieving an apt vehicle. According to the categorization (or attributive category) theory of metaphor (Glucksberg, 2001; Glucksberg & Keysar, 1990), apt vehicles must not only have the intended property but also be a prototypical exemplar of

that property. For example, consider the topic “rumor” and the property “quickly spreads from person to person.” People have to identify an appropriate vehicle to express by metaphor that a rumor quickly spreads from person to person. This property is true of a number of things such as “virus,” “swine flu,” and “louse,” but a virus is a prototypical exemplar of the category “things that quickly spread from person to person.” Hence, the metaphor “The rumor is a virus” seems to be more apt than “The rumor is a swine flu” and “The rumor is a louse.”

The research question to be answered here is how people identify or select a vehicle that accomplishes their communication purposes. This question can be rephrased as how the process of searching a set of things (i.e., search space) for a vehicle differs according to whether explanatory metaphors or literary metaphors are intended. To tackle this problem, we consider the observed differences between explanatory and literary metaphors. Some studies have found that semantic aptness (Steen, 1994; Utsumi, 2005), clarity (Gentner, 1982), and interpretive richness (Gentner, 1982; Utsumi, 2005) are distinctive properties for distinguishing between explanatory and literary metaphors. Explanatory metaphors are more apt (or appropriate) and clearer than literary metaphors, while literary metaphors are interpretively richer than explanatory metaphors. These findings suggest that semantically apt and clear vehicles may be preferably searched for in producing explanatory metaphors, while less apt vehicles that enrich the metaphorical meaning may be searched for in producing literary metaphors. According to the attributive category theory, vehicles of apt metaphors are prototypical members of the category characterized by the intended property of the topic (Glucksberg & Keysar, 1990). On the other hand, for a metaphor to be semantically rich and involve a number of metaphorical interpretations, its vehicle must be less prototypical because highly prototypical vehicles evoke only the intended property.

From these discussions, we can derive the following hypothesis about the process of metaphor production:

**Hypothesis about process:** *Only prototypical members of the category are searched for a vehicle during the production of explanatory metaphors, while less prototypical members are also considered to generate literary metaphors.*

This hypothesis presupposes that people first search prototypical members of the category before searching less prototypical members, regardless of discourse goals (e.g., Giora, 2003; Rosch & Mervis, 1975). Hence, this hypothesis implies that when producing explanatory metaphors, they do not have to search less prototypical members, because prototypical members are sufficient for apt vehicles. However, when producing literary metaphors, people have to search less prototypical members after prototypical members are activated.

The hypothesis about process implies another hypothesis about the metaphors (or vehicles) produced.

**Hypothesis about products:** *More prototypical and apt vehicles are chosen for explanatory metaphors than for literary metaphors.*

Considering that prototypicality and other related properties such as conventionality and familiarity can be classified into a more general notion of salience (Giora, 2003), it is also predicted that conventional and familiar vehicles are preferably chosen for explanatory metaphors. In addition, metaphor aptness refers to the extent to which the vehicle’s metaphoric category captures an important feature of the topic, and thus it reflects the similarity between the vehicle and topic of a metaphor (e.g., Chiappe & Kennedy, 1999). Hence, we also predict that vehicles chosen for explanatory metaphors are more similar to the topic than those chosen for literary metaphors.

In this paper, we test these hypotheses through two experiments, namely, an offline generation experiment and an online priming experiment. In the metaphor generation experiment (i.e., Experiment 1), we examined the validity of the hypothesis about products by analysing the vehicles generated for explanatory or literary metaphors. We compared the vehicles for explanatory metaphors and literary metaphors in terms of several factors: vehicle prototypicality, metaphor conventionality, metaphor aptness, topic-vehicle similarity, vehicle familiarity, vehicle word frequency, and vehicle imageability. In the online priming experiment (i.e., Experiment 2), we used a priming paradigm to test the hypothesis about the internal process of metaphor production, particularly to examine what words (or concepts) are activated during identifying an appropriate vehicle. In the priming experiment, participants were presented with a topic (i.e., an incomplete metaphorical sentence) and its property as a prime and asked to determine a vehicle appropriate for a given discourse goal. Afterwards, a target word was presented and participants were asked to make a lexical decision about it. The target conditions were a word that was highly prototypical of the category made up of the property, a word that was less prototypical of the category, and a control word unrelated to the property.

It must be noted here that the previous studies mentioned earlier analysed only the products of metaphor production using an offline paper-and-pencil experiment paradigm; they did not directly examine the online processes of metaphor production. To the best of our knowledge, this is the first study to apply an online priming paradigm to the study of metaphor production.

## Experiment 1

In Experiment 1, we tested the hypothesis about the product by collecting metaphor vehicles in a metaphor generation task and the ratings of their properties in a vehicle rating task.

### Method

**Participants** Forty undergraduate and graduate students participated as volunteers. All participants were native speakers of Japanese.

**Materials** Twenty pairs of a topic and a property to be attributed to the topic were used for the experiment. Topic words were selected from Japanese abstract nouns comprising two kanji characters, and their properties were expressed in a Japanese short phrase referring to a salient feature of the

topic. In order to eliminate an undesirable effect of the abstractness of the topic words on the process of categorization (Glucksberg & Keysar, 1990), we equalized the degree of abstractness of the topic words by choosing them from abstract categories of words at almost the same depth (i.e., depth of 7 or 8) in the hierarchical structure of the Japanese thesaurus. For example, the topic word “plan” (“*keikaku*” in Japanese) was paired with the property “does not always go as scheduled” (“*yotei doori-ni ikanai*” in Japanese).

**Procedure** This experiment comprised two tasks, namely a metaphor generation task and a vehicle rating task.

The metaphor generation task was conducted by 20 participants. Each participant was assigned all the 20 topic-property pairs, one half of which were used to generate explanatory metaphors and the other half of which were used to generate literary metaphors. Topic-vehicle pairs were counterbalanced across conditions so that each pair appeared 10 times in both conditions. The presentation order of the pairs in each group was randomized for each participant. Participants, who were run individually, were seated in front of a computer screen. They were first given an overall instruction of the experiment and presented with four practice trials (two for explanatory metaphors and two for literary metaphors) followed by two groups of 10 experimental trials. In the explanatory metaphor condition, participants were instructed to generate a vehicle that clearly explains the given property of the topic, while in the literary metaphor condition they were instructed to generate a metaphor aesthetically pleasing enough to use in literary works. On each trial, they were presented with a sentence frame including a topic (e.g., “A plan is (like) a \_\_\_\_\_”) and a property (“does not always go as scheduled”) in the center of the screen, and asked to generate an apt vehicle that completes the sentence at their own pace. When participants came up with a suitable vehicle, they indicated it by pressing the appropriate key on the keyboard. Afterwards, they typed the vehicle as quickly as possible. Reaction times were measured from the onset of the topic-property pair until the appropriate key was pressed (metaphor production time), and from the key press until the input of the vehicle was completed (vehicle typing time).

In the vehicle rating task, another 20 participants were presented with all the 20 topic-property pairs and their vehicles generated (i.e., metaphors and their property attributed to the topic) in the metaphor generation task. They were asked to rate each metaphor or vehicle on the following four 7-point scales: vehicle prototypicality (7 = *prototypical*, 1 = *not at all prototypical*), metaphor conventionality (7 = *conventional*, 1 = *novel*), metaphor aptness (7 = *apt*, 1 = *not at all apt*), and topic-vehicle similarity (7 = *similar*, 1 = *dissimilar*).

## Results and Discussion

First, we analysed the metaphor production time for explanatory and literary metaphors in the metaphor generation task. We eliminated from the analysis extreme outliers (i.e., production times shorter than 2s or longer than 40s, and production times of the trial whose vehicle typing times were longer than 30s), and averaged the remaining production times. As

Table 1: Means (*M*) and standard deviations (*SD*) of seven factors of explanatory and literary metaphors in Experiment 1

Factor	Explanatory		Literary	
	<i>M</i>	<i>SD</i>	<i>M</i>	<i>SD</i>

Vehicle imageability*	5.05	0.33	5.32	0.44

\* $p < .05$ . \*\* $p < .01$ . \*\*\* $p < .001$ .

a result, literary metaphors ( $M=77.39s$ ,  $SD=50.18s$ ) took longer to generate than explanatory metaphors ( $M=55.82s$ ,  $SD=29.74s$ ). This difference was marginally significant in the participant analysis,  $F_p(1, 19) = 4.18$ ,  $p = .055$ , although not significant in the item analysis,  $F_i(1, 19) = 2.13$ ,  $p > .1$ . (Note that, in all the ANOVAs reported in this paper, the data were analyzed by participants  $F_p$  and by items  $F_i$ .) This result is consistent with the hypothesis about the production process, in that people must search less prototypical members of the category after searching prototypical members, and consequently require more time to generate literary metaphors than explanatory metaphors. Note, however, that this result may not be reliable enough to warrant the hypothesis, because we had no efficient methods for confirming that participants really spent all the time producing metaphors. (Hence, Experiment 2 was conducted to collect reliable data on the internal process of metaphor production.)

We then compared the explanatory and literary metaphors generated in terms of four factors (i.e., vehicle prototypicality, metaphor conventionality, metaphor aptness, and topic-vehicle similarity). Table 1 shows the mean rating values of these four factors for explanatory and literary metaphors. Explanatory metaphors were rated as significantly higher on all the four factors than literary metaphors,  $F_p(1, 19) = 44.24$ ,  $p < .001$ ,  $F_i(1, 19) = 9.44$ ,  $p < .01$  for vehicle prototypicality;  $F_p(1, 19) = 1256.76$ ,  $p < .001$ ,  $F_i(1, 19) = 16.76$ ,  $p < .001$  for metaphor conventionality;  $F_p(1, 19) = 4.76$ ,  $p < .051$ ,  $F_i(1, 19) = 3.70$ ,  $p = 0.70$  for metaphor aptness; and  $F_p(1, 19) = 23.53$ ,  $p < .001$ ,  $F_i(1, 19) = 8.49$ ,  $p < .01$  for topic-vehicle similarity. These results are entirely consistent with the hypothesis about products, confirming that more prototypical and apt vehicles are chosen for explanatory metaphors than for literary metaphors.

Furthermore, we exploratorily analysed three additional factors of vehicle words — i.e., vehicle word familiarity, vehicle word frequency, and vehicle word imageability — that may differ between explanatory and literary metaphors. These values were derived from the database of Japanese lexical properties “Nihongo No Goi Tokusei.” In this database, the familiarity and imageability of a word were given as the mean rating scores on a 7-point scale ranging from 1 to 7, and the frequency of a word was given as the number of times the word occurred in a newspaper corpus. In the analysis, these

scores were used for vehicle familiarity and imageability, and the common logarithm of the frequency score was used for vehicle word frequency. The last three rows of Table 1 show the mean values of these three factors across vehicle words. Two out of three factors were significantly different; the vehicles of literary metaphors were more familiar and imageable than those of explanatory metaphors,  $F_i(1, 19) = 5.25, p < .05$  for vehicle familiarity; and  $F_i(1, 19) = 5.52, p < .05$  for vehicle imageability. The finding on vehicle imageability is intuitively acceptable, because literary works often evoke mental imagery, although Katz, Paivio, and Marschark (1985) found an opposite result that the vehicles of poetic metaphors were less imageable. On the other hand, the finding of vehicle familiarity is seemingly surprising, but can be explained by the assumption that the use of familiar words as a vehicle may enrich the interpretation of metaphors. Note that this finding is consistent with the finding of Katz et al. (1985) that poetic metaphors were rated as being more familiar.

## Experiment 2

In Experiment 2, we tested the prediction about the metaphor production process using a priming paradigm, in which an incomplete metaphorical sentence was presented first with the property to be attributed to the topic, and the task was to make a lexical decision about a target word presented after the metaphorical sentence. The target conditions were a word highly prototypical of the category characterized by the property (HPT), a word less prototypical of the category (LPT), and a control target (CNT) that is unrelated to the metaphor.

Faster lexical decisions in comparison with the CNT indicate online activation. If only the prototypical members of the category are searched for a metaphor vehicle, the HPT would be faster to make a lexical decision than the CNT, but the LPT would not be faster. If less prototypical members are also searched, both the LPT and HPT would be faster than the CNT. Hence, if our hypothesis about the process is right, only the HPT would be facilitated when explanatory metaphors are intended, while both the HPT and LPT would be facilitated when literary metaphors are generated.

## Method

**Participants** Fifty-four undergraduate and graduate students participated as volunteers. All participants were native speakers of Japanese.

**Materials** Thirty Japanese pairs of a topic and a property attributed to the topic (including all the 20 pairs used in Experiment 1) were used as primes. For each prime pair, three target words (i.e., HPT, LPT, and CNT) comprising two kanji characters were prepared. The HPTs and LPTs were selected on the basis of ratings collected from independent groups of participants in a norming study. The CNTs were selected randomly from a dictionary so that they were unrelated to both the topic and the property, and their word frequency was approximately equal to that of the HPTs and LPTs.<sup>1</sup> For exam-

ple, the pair of the topic “all-night activity” (“*tetsuya*”) and its property “unhealthy” (“*karada ni aku eikyo wo ataeru*”) was combined with the HPT “drug” (“*mayaku*”), the LPT “edacity” (“*oogui*”), and the CNT “speech” (“*enzetsu*”). In addition, another 20 topic-property pairs were prepared and used as filler sentences for nonword targets.

**Norming study** For each of the 30 topic-property pairs, six words (comprising two kanji characters) were prepared that referred to an object or a concept with that property but different degree of prototypicality. Ten undergraduate students rated these words on the 7-point scale of prototypicality ranging from 1 (*not at all prototypical*) to 7 (*prototypical*). For each topic-property pair, the word with the highest rating was selected as an HPT, and the word rated as the lowest of the words with the prototypicality degree of 4 (i.e., the midpoint) or higher was selected as an LPT. The prototypicality rating of the HPTs ( $M = 5.91, SD = 0.51$ ) was significantly higher than that of the LPTs ( $M = 4.37, SD = 0.35$ ),  $F(1, 29) = 211.23, p < .001$ , confirming that LPTs and HPTs were appropriately selected.

**Procedure** A within-participants design was used with each participant processing all the 50 topic-property pairs (i.e., 30 pairs with word targets and 20 pairs with nonword targets) under all conditions. The 50 pairs were equally divided into two groups, each of which comprised 15 pairs with word targets and 10 pairs with nonword targets. One group was used to generate explanatory metaphors and another group was used to generate literary metaphors. Topic-vehicle pairs with word targets were counterbalanced across all conditions (i.e., two conditions of discourse goal and three target conditions) so that each pair appeared an equal number of times in all conditions. The presentation order of two groups of discourse goals (i.e., whether explanatory or literary metaphors were generated first) and the order of the pairs in each group were randomized for each participant.

Participants, who were run individually, were seated in front of a computer screen. They were first given an overall instruction of the experiment and then presented with four practice trials (two for explanatory metaphors and two for literary metaphors) followed by two groups of 25 experimental trials. On each trial, they were presented with a sentence frame with a topic in the subject position (“A plan is (like) a \_\_\_\_\_”) and a property (“does not always go as scheduled”) as a prime in the center of the screen for 7000 ms and asked to consider an appropriate vehicle word to fill in the blank. A target word (HPT, LPT, CNT, or nonword) was then presented 500ms after the offset of the topic-property pair. Participants were asked to decide whether the target word was a word or a nonword as quickly as possible; they indicated decision by pressing the appropriate key on the keyboard. Finally, they typed the vehicle that occurred to them before the lexical decision. Reaction times were measured from the onset of the target word until the appropriate key was pressed.

## Results and Discussion

Only reaction times of correct decision were used in the analysis. In addition, reaction times greater than 10,000ms were

<sup>1</sup>The mean logarithms of word frequency score were 3.41 for the HPT, 3.62 for the LPT, and 3.60 for the CNT. They were not significantly different,  $F(2, 58) = 0.492$ .

Table 2: Means (*M*) and standard deviations (*SD*) of correct lexical decision times in milliseconds for Experiment 2

Metaphor condition	HPT (High Prototypicality)			LPT (Low Prototypicality)			CNT (Control)	
	<i>M</i>	<i>SD</i>	<i>DIF</i>	<i>M</i>	<i>SD</i>	<i>DIF</i>	<i>M</i>	<i>SD</i>
Explanatory	1450	550	51	1474	584	27	1501	727
Literary	1431	475	155	1303	420	283	1586	743

Note. *DIF* = difference from control target.

eliminated from the analysis.

Table 2 shows mean lexical decision times and standard deviations for the correct “yes” responses. The time difference (*DIF*) from the CNT indicates the extent of a priming effect. In the explanatory metaphor condition, the HPT produced a moderate priming effect (51ms faster than the CNT), but the LPT showed only a small priming effect (27ms faster). On the other hand, in the literary metaphor condition, both targets showed a much larger priming effect. In particular, the priming effect of the LPT (283ms) was larger than that of the HPT (155ms), indicating that less prototypical exemplars of the category were activated during the production of literary metaphors. These results are entirely consistent with our hypothesis that only prototypical members of the category are searched for a vehicle during the production of explanatory metaphors, while less prototypical members are also considered to generate literary metaphors.

To confirm these differences statistically, we conducted a two-way ANOVA of Target (HPT, LPT, or CNT)  $\times$  Discourse goal (explanatory or literary) on lexical decision times. These two factors were within participants and within items. First of all, the main effect of Discourse goal was not significant in either analyses, but the main effect of Target was significant in the participant analysis,  $F_p(2, 106) = 4.54, p < .05$ . Post-hoc pairwise comparisons showed that the priming effect of the LPT was significant ( $p < .05$ ) and the priming effect of the HPT was marginally significant ( $p = .051$ ). This result indicates that discourse goals did not affect the overall processing time of lexical decision and the priming effect was observed in this experiment. It confirms that this priming experiment was successful and the priming methodology can be applied effectively to the study of metaphor production.

The most important result was that the interaction between two factors was significant in the participant analysis,  $F_p(2, 106) = 3.40, p < .05$ , although not significant in the item analysis. The nature of this interaction was that, the simple main effect of Target was significant in the literary metaphor condition,  $F_p(1, 159) = 4.57, p < .05$ , but not significant in the explanatory metaphor condition. Post-hoc pairwise comparisons ( $p < .05$ ) revealed that both the LPT ( $M = 1303$ ms) and HPT ( $M = 1431$ ms) were significantly faster than the CNT ( $M = 1586$ ms). Again, these results are consistent with the hypothesis of this paper, although the absence of a significant priming effect of the HPT in the explanatory metaphor condition was not consistent with the hypothesis.

## General Discussion

The two experiments reported in this paper provided empirical evidence in favor of our view that discourse goals of metaphor affect the process of metaphor production. Specifically, we focused on two types of metaphors — i.e., explanatory metaphors and literary metaphors — that accomplish different discourse goals, and demonstrated that the production of literary metaphors required activation of both prototypical and less prototypical members of the category characterized by the topic property, while the production of explanatory metaphors did not. This processing difference leads to the finding on the products that explanatory metaphors generated in the metaphor production experiment were more prototypical than literary metaphors. In addition, it was found that explanatory metaphors were more conventional and apt, and had higher topic-vehicle similarity, while the generated vehicles for literary metaphors were more familiar and imageable.

The finding that less prototypical members of the category were activated during the processing of literary metaphors and as a result less prototypical vehicles are selected for literary metaphors is especially interesting, because it indicates that some metaphors cannot be explained by the attributive category theory of metaphor (Glucksberg, 2001; Glucksberg & Keysar, 1990). We have demonstrated elsewhere that the comprehension of predicative metaphors (i.e., figurative expressions that involve the metaphorical use of a verb or an adjective) cannot be explained by the attributive category theory of metaphor, and proposed an indirect categorization theory of metaphor (Utsumi & Sakamoto, 2007, 2011). The finding of this study suggests a possibility that some nominal metaphors (in particular, literary metaphors) may be processed by an indirect categorization or other mechanisms.

On the other hand, the finding that prototypical members were not activated during the production of explanatory metaphors is not consistent with the hypothesis. One possible explanation of this result would be that the process of identifying a vehicle for explanatory metaphors was so rapid that prototypical members were no longer activated 7500 ms after the onset of the prime. To test this possibility, we must repeat a priming experiment by varying the stimulus-onset asynchrony (SOA) of prime and target, which is left for future research.

The discourse goals of metaphorical or figurative expressions are affected by their grammatical form, i.e., whether figurative comparisons are expressed in metaphor form “An X is a Y” or in simile form “An X is like a Y.” Glucksberg and Keysar (1990) argued that metaphors are more forceful

than similes and alert an addressee that a specific set of properties is intended. Roberts and Kreuz (1994) demonstrated that metaphors and similes differ in that metaphors are used to add interest, but similes are used to deemphasize. If the discourse goals really affect the process of metaphor production as demonstrated in this paper, these pragmatic differences between metaphor and simile imply that the grammatical form has an important influence on the process of metaphor production. Furthermore, a number of studies have revealed that several properties addressed in Experiment 1 (e.g., aptness, conventionality, topic-vehicle similarity) determine the preferred form of figurative comparison (e.g., Bowdle & Gentner, 2005; Chiappe & Kennedy, 1999; Jones & Estes, 2006). Hence, the finding of Experiment 1 may serve to explain the relation between the grammatical form and the production process.

Computational modeling is also an efficient methodology for the study of metaphor production. Recently, computational studies based on a semantic space model such as latent semantic analysis (LSA) have addressed metaphors and shed new light on the process of metaphor comprehension (e.g., Kintsch, 2000; Utsumi, 2011; Utsumi & Sakamoto, 2007). In particular, the predication algorithm in a semantic space model proposed by Kintsch (2000) can embody the attributive category theory, and has been shown to achieve good performance of simulating the process of metaphor comprehension. It follows that the study of metaphor production can also benefit from the same computational modeling framework. For example, the predication algorithm computes the meanings of metaphors by combining neighbors of the vehicle (i.e., word vectors similar to the vehicle vector) with the topic and the vehicle. The process of metaphor production can also be modeled in the same way; an appropriate vehicle can be selected from the neighbors of the vector for the metaphorical meaning expressed by a given topic-vehicle pair, and a search space can be manipulated by varying the number of and quality of neighbor vectors. Indeed, Chiappe and Chiappe (2007) attempted to explain their findings on metaphor production using the predication algorithm.

These research topics for advancing the study of metaphor production are worth pursuing in further research.

## Abstract

Humans perform visual search fairly efficiently, finding targets within only a few fixations. Data from eye-tracked participants was subjected to a fixation by fixation analysis to pinpoint why participants tended to make fewer fixations than would be expected by chance. The goal of this paper is to present a computational model that performs visual search as efficiently as humans. The model varied several components that may have aided visual search: memory, search strategy, and degree of parafoveal vision. Two dependent measures were used to evaluate the model: number of fixations to find the target and the distribution of saccade amplitudes. The best fitting model suggested that the biggest contribution to efficient search came from larger parafoveal vision. Search strategy, however, accounted for the distribution of saccade amplitudes.

**Keywords:** visual search; model; memory; parafovea

## Introduction

Visual search is ubiquitous. Whether we are locating an item in the grocery store, trying to find our car in a busy parking garage, or looking for an important piece of information on a web page, visual search is involved in most every task we perform. In this paper we discuss two critical components of efficient serial visual search, *the number of fixations taken to find a target* and the *strategy* used to move the eyes around the screen. Our emphasis is on *active vision* (Findlay & Gilchrist, 2003) to examine the search strategies used by people as they search for items in their environment. The goal of the current work was to devise a computational cognitive model that was capable of reproducing human visual search efficiency. A set of process models varied different cognitive capacities theorized to affect search efficiency (i.e., deliberate strategy, memory size and parafovea size) to explore the parameter space associated with serial search efficiency.

Visual search as a paradigm has been studied meticulously for the better part of the last 50 years. In that time several notable models of visual search have been proposed (Duncan & Humphreys, 1989; Treisman & Gelade, 1980; Wolfe, 1994). The paradigm itself consists of the detection of a target among a varying number of distractors. Search time has been found to be influenced by number of distractors (set size), similarity of distractors and targets, and number of features used to define a target (Davis & Palmer, 2004; Wolfe, 2003). The ease with which a target can be detected is often varied and response time data is typically used as the dependent measure.

While knowing how quickly visual information is found is important, understanding *how* that information is found is just as important—“vision is a tool, not the task” (Pelz &

Canosa, 2001, p. 3588). For this reason, the task our participants performed was not visual search, but a decision making task that, like grocery shopping or finding the car in the parking garage, just happened to require visual search. The vast majority of visual search studies have largely ignored the process of visual search, with a few notable exceptions (Zelinsky, Rao, Hayhoe, & Ballard, 1997; Araujo, Kowler, & Pavel, 2001; Unema, Pannasch, Joos, & Velichkovsky, 2005; Zelinsky, 2008). This is problematic because “visual search is more than the time taken by an observer to detect a target and press a button. It is instead a richly complex behavior having both a spatial and temporal dynamic” (Zelinsky et al., 1997, p. 448). By relying on only response time data, visual search paradigms have essentially thrown out the spatiotemporal contingencies that propel the search process. In recent years, however, a considerable effort has been put forth to connect eye movements with the underlying cognitive process (Liversedge & Findlay, 2000).

Zelinsky (2008) analyzed eye movements from participants who searched for common household items on a tabletop. The display was limited to six stationary locations where objects could appear and on each trial there was either one, three or five items to search through. Results demonstrated that eye movements were directed towards geometric centers of progressively smaller groups of objects. It should be noted that due to the limited search display (only six possible locations and up to five items visible on any given trial) the eye movement sequences were relatively short and, in practice, limited to the first three fixations. Thus, a study which has a more complex object structure and which examines longer sequences of fixations may better elucidate the visual search process. One study that looked at longer fixation traces found that fixations and saccades progress in a coarse-to-fine strategy whereby fixation durations increase while saccade amplitudes decrease as search continues (Over, Hooge, Vlaskamp, & Erkelens, 2007). Over et al. (2007) found that participants initially attended to general properties of the search environment (i.e., the lay of the land) but, as the trial progressed, gradually paid attention to specific, detailed information.

One question we can ask is whether the layout of the display facilitates and/or guides the visual search process. Others have found that external landmarks aid visual search by reducing the number of refixations on previously viewed items (Peterson, Boot, Kramer, & McCarley, 2004; Myers & Gray, 2010). In previous work, we found that segmenting

the visual search display into perceptual clusters provides a starting point for understanding where the eyes may go (Veksler & Gray, 2011). The modeling work presented here utilizes the perceptual segmentation found in our previous work to explore the efficiency of serial visual search within this paradigm. Furthermore, two metrics are used to compare human and model data: number of fixations to locate the target and the distribution of saccades around the screen during search.

The role of memory within visual search has also been greatly debated. In some instances, researchers have inferred from response time data that memory is not utilized during search (Horowitz & Wolfe, 2003; Melcher & Kowler, 2001). In other instances, it has been shown that visual search is guided by memory for previously viewed items (Korner & Gilchrist, 2007; Peterson, Beck, & Wong, 2008, 2001), that there is some memory for the search path (Dickinson & Zelinsky, 2007), and that more new locations are searched as opposed to old (Beck, Peterson, Boot, Vomela, & Kramer, 2006; McCarley, Wang, Kramer, Irwin, & Peterson, 2003). The current work also explores the role of memory within visual search, by varying the number of previously seen items that the model avoids re-fixating during search.

In summary, we use human data and computational modeling to explore the combination of components that contribute to efficient serial visual search. The components explored include search strategy, amount of memory for previously seen items, and the effective field of view. Previewing our conclusions, the major contribution to search efficiency comes from a larger parafovea. Memory plays an important role in this task, though not as an important role as we might have expected. Search strategy was explored as human data indicated that participants did not move their eyes around the screen in a random fashion, but rather transitioned across clusters of items on the screen.

## Experiment

We explore the allocation of attention during visual search when search is a subtask of a larger decision making task. The larger task was composed of the following on each trial,

1. 20 targets (represented as two-digit numbers) appeared on a *radar* screen at random locations (left-side of Figure 1). Each two-digit target subtended a  $0.62^\circ$  of visual angle.
2. Participants were provided with a list of six targets (right-side of Figure 1) and told to determine which target had the highest threat value.
3. Participants had to locate each one of the targets on the radar screen (visual search) and click on it with the mouse.
4. The target's threat value appeared next to the target. The delay between clicking and appearance varied between groups – 1, 2, 4, or 8 seconds.

5. Participants held the number and threat value of the target with the “highest threat value so far” in memory as they continued to locate other targets in the list of six.
6. When they decided that they had found the target with the highest threat value (usually, but not always, after an exhaustive search), they selected that target (with the mouse) in the list on the right hand side, and clicked on the Choose button (at the bottom right of Figure 1).

Although participants searched through the display for multiple targets on any given trial, for purposes of this paper, only the first search through the display (until the first search target is found) will be reported and modeled.

## Method

Participants were divided into four conditions which varied the duration of how long they had to wait before information (threat value of target) appeared (1, 2, 4, or 8 s). All other aspects of the task remained the same across all participants.

Figure 1: Task environment.

**Participants** A total of 88 participants from Rensselaer Polytechnic Institute were run during the study. Of those, 12 were excluded because their valid eye data fell below 90%, and two were excluded because their accuracy scores fell below 3 standard deviations of the group mean resulting in 74 participants included in the analyses (57 males). There were 19 participants in two of the conditions and 18 in the other two. The mean age of all participants was 18.8,  $SD=0.85$ .

**Apparatus** The experiment was presented using a computer running Mac OS X on a 17 inch flat-panel LCD monitor set to 1024x768 resolution,  $39^\circ \times 25^\circ$  of visual angle at the distance at which participants sat from the screen. The software used for the experiment was written in LispWorks 5.0. An LC Technologies eye tracker was used to collect eye data during the study at a rate of 120Hz. A chin rest was used to help ensure the accuracy of recorded eye data. Eye data quality was checked after every block of 10 trials to ensure the eye tracker was functioning and participants remained calibrated.

**Procedure** Participants were run separately. After signing informed consent forms, participants were given task instructions, calibrated to the eye-tracker and asked to keep their chin in the chinrest throughout the duration of the experiment. They also had to fixate a fixation cross prior to each trial to ensure the eye-tracker’s accuracy.

Participants completed six blocks of 10 trials (60 trials total). A mandatory 60s break was included halfway through the study. A practice block of 5 trials was included prior to the 60 experimental trials during which time the experimenter remained in the room to ensure that participants understood how to do the task and that eye data remained valid. The experiment took  $\approx 40$  minutes to complete. Each trial proceeded as described in the beginning of the Experiment section.

## Results

The majority of participants tended to search for targets in the order presented on the right hand side of the display (top to bottom). Participants tended to locate the first target they were searching for after  $\approx 8$  fixations on radar items. Since the first search in a trial was not biased by any memory effects of having found a target on a previous search, it will be used for comparison to simulation model results.

**Number of Fixations to Find Target** Table 1 summarizes the average number of fixations to locate the target, by condition in the study. A one-way ANOVA was conducted and indicated that there was not a significant effect of condition on either the total number of fixations to find the target,  $F(3, 69) = 1.27, p = .29$ , or the number of unique fixations to find the target,  $F(3, 69) = 0.63, p = .60$ . Importantly, of the fixations shown in Table 1, roughly one target is fixated twice. This pattern suggests that participants were not necessarily maintaining all of the searched items in memory.

Table 1: Average number of total and unique fixations on radar items prior to finding first target in a trial.

Condition	N	Mean Total (SD)	Mean Unique (SD)
1	18	8.38 (1.6)	7.66 (0.86)
2	19	7.57 (1.06)	7.24 (0.75)
4	19	8.2 (1.48)	7.47 (0.93)
8	18	8.0 (1.19)	7.48 (0.87)

Collapsing over conditions, Figure 2 plots the cumulative probability of finding the first target selected. A two-way ANOVA (number of fixations as a repeated factor) was run to determine whether the lockout condition influenced search efficiency. There was a significant main effect of number of fixations,  $F(43, 2967) = 2847.23, p < .001$ , no interaction,  $F(129, 2967) = 0.95, p = .63$ , and no main effect of condition,  $F(3, 69) = 0.54, p = .66$  on the probability of finding the target within that number of fixations. Therefore all data from the different conditions was collapsed to be used for compar-

ison with the models.

Figure 2: Cumulative Probability of Finding the Target Within Number of Fixations.

Figure 2 shows the cumulative probability of finding the initial target within  $N$  fixations, aggregated across all 74 participants. This figure also suggests that about 50% of the time participants located the target within 8 fixations. For comparison purposes, Figure 2 also shows what would be expected by chance in a model that randomly searched the radar with either no memory (dashed line) for previously seen items or perfect memory (dotted line). As can be seen, participants find the target in fewer fixations (8 on average) than would be expected by chance (10 or half of the items on the screen). This suggests that accounting only for the amount of items held in memory (so as not to refixate them) during search is insufficient to model this efficiency.

**Eye Movements and Clusters** In prior work, we derived a perceptual clustering algorithm which utilized human judgments of clusters to segment the display (Veksler & Gray, 2011). Participants in that study judged items to be part of the same cluster if they were within  $3.28^\circ$  of visual angle of each other. The algorithm adds items to a single cluster if they are less than  $3.28^\circ$  of visual angle apart, further adding more items that fall within  $3.28^\circ$  of all the items in the cluster already until no more can be added. The segmented displays generated using this algorithm were then used to determine whether search is based on clusters of targets.

Figure 3 illustrates the probability within the human eye data of a participant remaining in any given cluster given the size of that cluster. Given the eye fixation transitions, three equations were derived to fit the transition probabilities in the human data and to be later used in the model that moves its

eyes around the screen.

- Likelihood of staying in a cluster given the size of the cluster is:

$$P(\text{Stay In Cluster}) = .3292 * \ln(\text{clustersize}) - .0266 \quad (1)$$

- If participants stay within a cluster, the likelihood of them looking at the closest item to the current fixation within the cluster is:

$$P(\text{Go To Closest In Cluster}) = 1.4324 * (\text{clustersize})^{-.776} \quad (2)$$

- If participants move their gaze outside of the cluster, the likelihood of them looking at the closest item outside of the cluster is:

$$P(\text{Go To Closest Outside Cluster}) = .1888 * e^{(.0577 * \text{clustersize})} \quad (3)$$

Figure 3: Probability of staying in the cluster on subsequent fixation. Distance First: prediction if participants always saccaded to closest item to current. Random: prediction if participant randomly saccaded around the screen.

**Distribution of Saccade Amplitudes** In addition to looking at the number of fixations that participants made to find the target, we also looked at the distribution of saccades (distances traveled by the eye between fixations). Figure 4 illustrates the distribution of saccade amplitudes in the human data (solid black line). As can be seen, the majority of saccades span about  $2.26^\circ$  of visual angle indicating participants moved their eyes to locations fairly close to each other. There is however, a smaller second mode around  $17^\circ$  indicating that

participants occasionally swept their eyes across larger areas of the screen. It is beyond the scope of this paper to address these larger sweeps or when they tended to occur.

## Model

Several visual search models were explored and simulated in order to model the efficiency of human serial visual search. There were three parameters that were manipulated in the modeling of the visual search process in this task. The first was the degree to which memory for previously seen items was used in the search process. The memory component essentially avoids shifting gaze to a target if it has been previously fixated within the last  $N$  fixations. The number of items held in memory was varied between 1(no memory)-19(perfect memory). It should be noted that even though we only looked at the first search within the trial, there may still be memory operating during search, particularly for previously searched locations.

The second parameter that was explored was the effective Field of View (FOV) that the model has. The model is able to shift its gaze to the target it is searching for if it notices it within its parafovea, typically about 2 to 6 degrees of visual angle around the current fixation (Reis & Judd, 2000). While the fovea is the high acuity region of the retina, up to about  $2^\circ$  of visual angle, the parafovea is a region in which acuity is not as high, with decreasing acuity as the eccentricity from the fovea increases. We explored values of 1,2,2.5, and 3 degrees of visual angle around the current fixation point providing an effective fovea+parafovea region (FOV) of 2, 4, 5, and 6 degrees, respectively.

The final manipulation had to do with the actual search strategy used. Three search strategies were explored: cluster-based, cluster-based with memory for clusters and random.

The cluster-based search model first segments the screen into several clusters based on prior empirical work (Veksler & Gray, 2011). These clusters are then used to guide the model's eye movements based on the cluster transition probabilities as per Equations 1-3. The model decides on each fixation whether or not it wants to shift attention away from the current cluster. It then decides with a certain probability to shift its gaze to either the closest item within the cluster or the closest item outside of the current cluster. The cluster-based model with memory for clusters also maintained memory for clusters it has already searched. Thus, when transitioning out of a cluster, it avoided looking to targets within previously searched clusters.

The random model search strategy is used as a baseline model. This model disregards the placement of the items on the screen and randomly chooses a target from the set of targets in the radar. The memory component was varied from a random model with no memory to one with perfect memory for targets already seen. One limitation of this model is that because the model disregards placement of items on the screen, its shifts of gaze can span long distances resulting in inefficient eye movements.

There were  $19(\text{memory store}) \times 4(\text{FOV angle}) \times 3(\text{strategies})$  models run on the radar targets used by participants in the study. Each model was run on each of the trials of human data and the number of fixations along with saccade amplitudes that were made prior to finding the first target were recorded to be compared with human data from the same set. In all, each model was run on 4559 trials.

## Results

The simulations were run to determine which models could find the targets in the radar using the same number of fixations that participants used. The cumulative likelihood of finding the first target in a trial within  $N$  fixations was derived for each model and the human data and then compared. As an additional dependent measure, fixation transitions were recorded for each model and the distribution of saccade amplitudes was compared with human data.

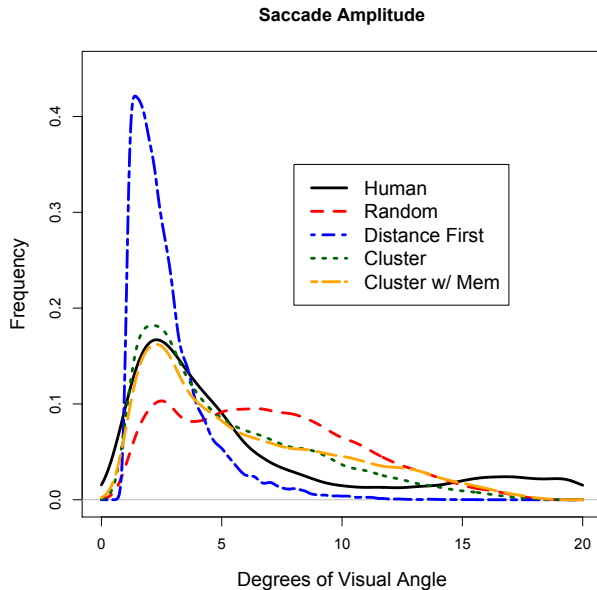

Figure 4: Distribution of saccade amplitudes across all eye data for humans and models. Models depicted are best fitting.

Search efficiency was greatly improved by the inclusion of a parafovea in all of the models (a FOV of 4, 5 or 6 degrees of visual angle). Without a parafovea (57 models), the best fit that can be achieved between human and model data has an  $\text{RMSE}=0.11$  and an  $\text{R}^2=.92$ . The model that achieves this is the cluster search model with cluster memory and memory for 16 individual targets. If we include a parafovea, 74% of the parafovea-included models surpass this fit. Therefore, the models that were next compared all had varying degrees of a parafovea.

Based on RMSE, the top 15 models all had an effective FOV of 5 degrees. The top cluster-based search model that utilized cluster memory had a memory of 4 items,  $\text{RMSE}=0.018$  and an  $\text{R}^2=.99$ . For comparison, the top

Table 2: Best fitting simulation model in each search strategy, comparing cumulative number of fixations. FOV: effective field of view in degrees of visual angle.

Search Strategy	Memory	FOV (°)	RMSE	$\text{R}^2$
Random	1	2	0.19	0.83
Random	19	2	0.04	0.90
Random	14	5	0.017	0.99
Cluster	15	6	0.025	0.99
Cluster w/ Mem	4	5	0.018	0.99

Table 3: Simulation models' results comparing saccade amplitude distributions. FOV: effective field of view in degrees of visual angle.

Search Strategy	Memory	FOV (°)	RMSE	$\text{R}^2$
Random	13	6	0.0009	.44
Distance First	16	6	0.0015	.75
Cluster	4	6	0.0004	.90
Cluster w/ Mem	8	6	0.0004	.86
Random	14	5	0.0010	.36
Cluster	15	6	0.0004	.88
Cluster w/ Mem	4	5	0.0005	.82

cluster-based search model that did not utilize cluster memory needed to remember 15 items and required a FOV of 6 degrees to attain good fit,  $\text{RMSE}=0.0252$  and an  $\text{R}^2=.99$ . The top random search model needed a memory for 14 items and a FOV of 5 degrees,  $\text{RMSE}=0.017$ ,  $\text{R}^2=.99$ . Table 2 summarizes the results of the model comparisons along with baseline comparison to the two models depicted in Figure 2. For conciseness only the best fitting models are reported.

These results suggest that for a model to be able to search as efficiently as human participants, it needs to have some amount of a parafovea and either a large memory for individual items or a small memory for individual items along with some memory for clusters searched.

Next we compared the distribution of saccade amplitudes over the course of the search in each of the models. As an added baseline, a distance-first model was run to show what would happen if the model always saccaded to the closest item to its current point of gaze. Figure 4 depicts the human data along with the best fitting models using each of the search strategies. Table 3 provides statistics for both the best fitting models (top panel) as well as the best fitting models from the cumulative number of fixations comparison (bottom panel). In terms of modeling the distribution of saccade amplitudes, both of the cluster-based search models fit the human data well. The random search and distance first model, however, have much poorer fits.

## Discussion

This work was intended to provide a computational model of the efficiency of serial visual search found in humans. Two dependent measures were used to evaluate the models generated: efficiency of search (number of fixations to locate a target) and the distribution of saccade amplitudes (how far the eye moved between fixations). It was found that incorporating a larger parafovea contributed a great deal to the efficiency with which the model was capable of finding the target. The inclusion of a memory for clusters allowed the model to have less of a need for a larger memory store for individual items searched. The cluster-based search model was also much better able to reproduce the distribution of saccade amplitudes found during human visual search, suggesting the efficacy of a search strategy based on segmentation of a display into clusters.

One limitation of the current cluster-based model and direction for future work is accounting for the longer spanning saccades as when human participants transition out of a cluster (i.e. moving to the opposite side of the screen). Another is addressing the discrepancy between the best fitting models according to the two dependent measures.

## Acknowledgments

## Abstract

The application of conventional phylogenetic techniques for inferring cultural history is problematic due to differences in the nature of information transmission in biological and cultural realms. In culture, units of transmission are not just measurable attributes, but communicable concepts. Therefore, relatedness amongst cultural elements often resides at the conceptual level not captured by traditional phylogenetic methods. This paper takes a cognitively inspired approach to analyzing material cultural history. We show that combining data for physical attributes of cultural artifacts with conceptual information can uncover cultural influences among different ethnolinguistic groups, and reveal new patterns of cultural ancestry. Using the Baltic psaltery, a musical instrument with a well-documented ethnographic and archaeological record, we recovered a previously unacknowledged pattern of historical relationship that is more congruent with geographical distribution and temporal data than is obtained with other approaches.

**Keywords:** archaeology; artifacts; cladistics; cultural evolution; material culture; network model; phylogeny

## Introduction

The artifacts we put into the world reveal much about the minds that conceived them. The evolutionary history of human artifacts tells the story of how our thoughts, beliefs, and understanding of the world we live in, has unfolded over the ages. Using tools and techniques that include insights from cognitive science, we are starting to piece this exciting story together.

Phylogenetic approaches to reconstructing evolutionary patterns and processes, applied routinely in systematics, are increasingly applied not just to linguistics, but also elements of material culture, such as textiles, weapons, and musical instruments (*e.g.*, Collard, Shennan & Tehrani, 2006; Forster & Toth, 2003; Mace & Holden, 2005; Shennan, 2008; Whiten *et al.*, 2011). Originally developed in biology for inferring historical relationships among groups of organisms, phylogenetics makes use of assumptions about how information is organized and transmitted that reflects peculiarities of the biology world.

The direct transfer of methodology from biology to culture has raised the question about the extent to which meaningful parallels can be drawn between the processes of change in the two domains (*e.g.*, Eldredge, 2000; Gabora, 2006). Application of phylogenetics to material culture assume that the same (or analogous) causal processes operate in culture and nature. However, what is transmitted through culture is not just the objects themselves, but rather communicable perspectives and concepts, such as notions of complementarity (*e.g.*, between a mortar and pestle, which share no attributes but clearly are related), or competition for the same cultural niche (*e.g.*, spear, gun, rope, and so forth) that may or may not be reflected in the artifact design. Indeed, some claim that the differences between biological and cultural evolution are so insurmountable that insights obtained from biology are completely irrelevant in a cultural context (Moore, 1994; Dewar, 1995; Terrell, 2001). Others such as ourselves take a more moderate stance, arguing that well there are significant parallels as well as differences between biological and cultural systems, phylogenetic techniques have limited application to culture, and it is necessary to either significant modify existing approaches, or develop altogether new ones (Eerkens, Bettinger, & McElreath, 2005; Borgerhoff-Mulder *et al.*, 2006; Gabora, 1998, 2006, 2008; Nunn *et al.*, 2006; Tëmkin & Eldredge, 2007).

In a previous paper (Gabora *et al.*, 2011) we put forward a graph theory-based approach to modelling the evolution of cultural artifacts, and applied it to a well-studied set of artifacts: early projectile points from the Southeastern United States. This data set had previously been modelled using a phylogenetic approach (O'Brien, Darwent, & Lyman, 2001), and using an earlier version of the network-based approach, upon which our model is based (Lipo, 2005). The model included reticulate relationships as well as hierarchical groupings, and incorporated conceptual information to complement physical attribute data. We showed that incorporating conceptual information that is not typically captured by the phylogenetic analysis can significantly alter the inferred pattern of historical relationships amongst artifacts.

The current paper reports on new developments of the model, most notably, a means of evaluating the relative contributions of different types of data to historical inference. In addition, we apply the approach to a very different domain, thus demonstrating its generalizability.

## The Data Set

The experimental data set is a representative selection of Baltic psalteries, a traditional plucked stringed musical instrument distributed among Baltic, Finnic, and Slavic peoples of Northeastern Europe. Until recently, the Baltic psaltery remained an integral part of secular and ritual life, and has become a national symbol for every ethnic group that has it. The origin and historical development of the Baltic psaltery has been a controversial subject for over a century (reviewed by Raynolds, 1984) and remains so to this day (Povetkin, 1989; Haas, 2001; Tëmkin, 2004).

The data on psalteries consist of extensive descriptions of structural and ornamental features, and documented (or inferred) playing styles for 13 ethnographic (dated by 17-20 centuries) and two archaeological (dated by late 10-13 centuries) artifacts, representing major pertinent ethnolinguistic groups. The data set includes two Estonian (EST), two Finnish (FIN), three Latvian (LAT), three Lithuanian (LIT), three Russian (RUS), and two presumably Slavic archaeological instruments from Novgorod, northwestern Russia (NVG).

## The Conceptual Network Approach

In this section we outline our approach. We begin by summarizing how it models attributes and concepts. We then move on to the conceptually new contribution of this paper, the use of ‘perspectives’ to bias the network structure in culturally meaningful ways.

## The Structure of Attributes and Concepts

Following convention, concepts are indicated by all capital letters (PSALTERY), whereas an actual artifact, or instance of a psaltery is indicated with all small letters (psaltery).

The more superficial level of conceptual structure consists of what Rosch (1978) refers to as *basic level concept*, such as PSALTERY, which mirror classes of objects that share a broad range of perceivable attributes. These basic level concepts can be recursively differentiated. For example, a psaltery's attribute “strings” can be differentiated into “metal” or “nylon” depending on the type of the material the strings are made of. Each of these subordinate attributes can be further resolved by introducing their respective attributes, such as, for instance, “metal type,” “nylon type,” or “color.” Some attributes of the second degree may be shared by those of the first: both metal and nylon strings have color, but only metal strings are made from a specific metal type. Hence, a basic level concept can be represented as a root of a graph and its attributes arranged by levels of descriptive resolution. Because attributes at a given level can be connected to multiple attributes of levels above and below, the resultant structure contains both hierarchical and reticulate aspects.

Basic level concepts are generalized at a more abstract level as instances of superordinate concepts, such as MUSICAL INSTRUMENT. Superordinate concepts typically refer to multiple basic level categories (e.g., MUSICAL INSTRUMENT consists of both PSALTERY and CORNET).

## Conceptual Structure and its Representation

Each artifact is represented by a network of attributes consisting of reticulated hierarchies. The attributes can be physical or non-physical (conceptual). The total network of all available attributes constitutes the conceptual structure (Figure 1). Each artifact is represented by a subnetwork of the conceptual structure. (In a sense this is conceptually similar to phylogenetic approaches where all taxa and their attributes are described as arrays of specific character states in a character state data matrix.)

The conceptual structure introduced here is based on the state context property (SCOP) theory of concepts (Aerts & Gabora, 2005a, 2005b; Gabora & Aerts, 2002) and is equivalent to a simplified ontology (Sowa, 2000). We

Figure 1: A segment of the conceptual structure used in the Baltic psaltery analysis. Elements in square boxes represent physical attributes of artifacts. Elements in oval boxes correspond to conceptual attributes. Shaded boxes designate attributes associated with symbolic significance, i.e., those relevant to the “Symbolism” perspective (see text for details). Note that this perspective includes both conceptual and physical attributes. Inset shows an example of a Baltic psaltery.

incorporate the notion of context by introducing the notion of *perspective* (see next section), and use graph theory instead of operator theory to develop similarity metrics.

### Incorporation of Perspectives

Given the heterogeneity of attributes, (structural vs. ornamental, physical vs. conceptual, and so forth), it may be useful to be able to explore the effect of different sets of attributes on the evolutionary pattern. Depending on the perspective from which a given artifact is considered, the emphasis is placed on a particular set of attributes. For example, a musical instrument can be viewed as an art object, a product of craftsmanship, a sound-producing device, or a sacred symbol. Given a particular perspective, a set of attributes may include physical features (e.g., presence of a soundhole), conceptual non-physical descriptors (e.g., ritualistic function), or a mixture of both. Because physical and non-physical attributes represent different culturally relevant aspects of the artifact, including both types of data in the analysis can potentially produce a more comprehensive, and presumably, more realistic pattern of evolutionary history for a collection of artifacts as a whole.

This is accomplished by defining a *perspective*, a part of the conceptual structure that includes a predefined subset of attributes that may or may not be directly linked to each other. Multiple perspectives can be defined for a given conceptual structure, and they may or may not have attributes in common. In the analysis of the Baltic psalter, we defined three perspectives: (1) *Physical Attributes*, containing structural or decorative features of actual artifacts; (2) *Performance*, containing concepts related to music performance styles; and (3) *Symbolism*, containing concepts or physical attributes associated with sacred symbolism and ritualistic significance. Perspectives in the conceptual network approach are, in a sense, analogous to character partitions in biological phylogenetics.

### Reliability and Similarity

In the proposed approach, similarity among artifacts is assessed by pairwise comparison of their network representations. The comparisons can be made between entire sub-networks corresponding to complete representations of the two artifacts, or with respect to a particular perspective, or set of perspectives. To formalize this notion of similarity, we assume graph representations of two artifacts,  $a$  and  $a'$ , and a perspective  $p$ . We introduce two functions:

$$O(a, a', p) = |a \cap a' \cap p| \quad (1)$$

$$D(a, a', p) = |a \cap p| + |a' \cap p| - 2O(a, a', p) \quad (2)$$

where  $|x|$  is the number of vertices of  $x$ , and  $x \cap y$  is the set of common vertices between  $x$  and  $y$ .  $O(a, a', p)$  is the *overlap* and  $D(a, a', p)$  is the *divergence* between artifacts  $a$  and  $a'$  with respect to  $p$ . The overlap and divergence

account for the number of attributes included in  $p$  that are shared or non-shared, respectively, by  $a$  and  $a'$ .

Accounting for both the overlap and divergence is critical to determine the similarity of two artifacts. Overlap alone can lead to an overestimation of overall similarity in some situations, such as in a trivial case where one of two artifacts possesses just one attribute included in a particular perspective and this attribute is shared by another artifact that has a greater number of attributes included in the same perspective. In this case, the failure to account for divergence will erroneously interpret the complete overlap as absolute similarity between the artifacts with respect to the chosen perspective.

Some perspectives capture more of the overlap and divergence between artifacts than others. Indeed, a (non empty) perspective may include none of the attributes of the artifacts being compared, or it may include them all. In general, some portion of the total overlap and divergence between two artifacts is captured by a perspective. We define the *reliability*  $R(p, a, a')$  as the proportion of the overlap and divergence between artifacts  $a$  and  $a'$  given perspective  $p$  as follows:

$$R(p, a, a') = (O(a, a', p) + D(a, a', p)) / (|a| + |a'|) \quad (3)$$

Note that the entire conceptual structure can also be considered as a perspective. In this case, its reliability is equal to 1 for any given pair of artifacts. This is because it contains all possible concepts used to represent each artifact. Hence, the whole conceptual structure, and more inclusive perspectives in general, have greater reliability. However, the notion of reliability in itself may not be sufficient as an estimation of the perspective's effect on the similarity between artifacts. There may exist a small portion of the conceptual structure such that if considered as a perspective it would have small reliability, but which may nevertheless be vital for establishing the similarity of some artifacts. Therefore, given a set of perspectives  $P = \{p_1, \dots, p_n\}$ , we introduce a *perspective weight vector*,  $V = \{v_1, \dots, v_n\}$ , which gives the relative degree of importance of  $p$  in  $P$ , and defines the *similarity* between two artifacts  $a$  and  $a'$  with respect to  $P$  by the following formula:

$$S(P, V, a, a') = \sum_{i=1}^n v_i R(p_i, a, a') (O(a, a', p_i) - D(a, a', p_i)) \quad (4)$$

The *similarity*  $S(P, V, a, a')$  takes into account the overlap and divergence between their graph representations summed over all perspectives, each weighted by their respective reliability values and perspective weight vectors. Note that the greater the reliabilities of the perspectives in  $P$ , the greater the similarity between  $a$  and  $a'$ .

The approach provides a means of exploring the effect of individual perspectives on evolutionary inference. There are several ways of going about this, ranging in objectivity from fully automated, unbiased naive models to sophisticated expert-specified models that allow for incorporation of background information: (1) a *uniform*

*weights* model, which weighs all perspectives equally; (2) an *implied weighting* model, which weighs each perspective proportional to its reliability; (3) a *sensitivity* model, which explores a range of weights allowing for identification of most and least stable relationships; and (4) an *expert choice* model, which enables the user to specify unique weights (including removing a selected perspective from the analysis) to each perspective.

## Similarity Graph and Cultural History

A pairwise similarity matrix based on comparing all pairs of artifacts with respect to a chosen perspective (or set of perspectives), is used to compute a *similarity graph* where each vertex (node) corresponds to an artifact, and an edge implies that the extreme vertices of the edge are similar. The edge is labelled by the similarity weight between the two artifacts. The graphical representation of the similarity graph can subsequently be interpreted as a historical pattern of relationships amongst included artifacts. It is important to emphasize that the similarity graph is *not* a cultural phylogeny, but a mere representation of similarity among artifacts: it does not incorporate explicit actual cultural transmission models but provides an independent framework for establishing historical hypotheses that can corroborate or disagree with existing models of cultural change. We restrict ourselves to the *maximal similarity graph*, which connects each artifact to only those that have the highest similarity to it (in most cases, for each artifact there is only one most similar artifact). The maximal similarity graph provides an approximation to the artifact's true cultural history.

## Computational Implementation

The program we use to infer cultural lineages was developed using the object-oriented Java platform with extension packages for working with networks (JUNG). It allows for the creation of a conceptual structure by adding nodes (concepts) and edges (conceptual relationships). Perspectives and artifacts can be generated as well. One can specify the entries of the perspective weight vector using an array of sliders (one slider is automatically created for each perspective the user creates). Other software functions allow the user to export and import these structures for later use. The currently implemented default weighting scheme is the *implied weighting* model, which weighs each perspective proportional to its reliability. By modifying the perspective weights, the user can recompute the similarities, and visualize the resulting changes to the similarity graph. This enables exploration of the resulting similarity graphs found in different regions of perspective weight space.

## Results

We present the patterns of relationship obtained for the Baltic psalteries with respect to two perspectives: *Physical Attributes* and *Symbolism*. When only physical attributes of the psalteries are considered, the resulting similarity graph recovers clusters of instruments corresponding to

ethnolinguistic affinities with the exception of the Baltic instruments that appear to be more dispersed (forming three lineages; Figure 2A). This is consistent with previous results based on maximum parsimony analysis (Tëmkin, 2004; Tëmkin and Eldredge, 2007). On the other hand, when only symbolic aspects are taken into account, such sharp delineation based on the linguistic affinity becomes less evident and novel relationships emerge (Figure 2B). For example, in the former scenario, the Baltic instruments were linked to the Estonian (Finnic) ethnographic instruments, whereas in the latter they have no connection with the Estonian instruments, and display a novel connection with the Slavic instruments.

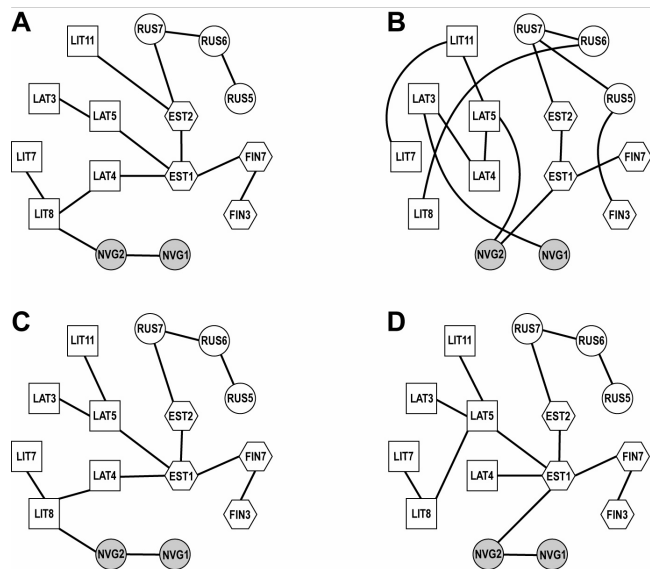

Figure 2. Similarity graphs based on the conceptual network analysis of Baltic psalteries under different perspective weighting schemes. (A) *Physical attributes*; (B) *Symbolism*; (C) *Physical attributes* and *Symbolism* (equal weights); (D) *Physical attributes* (25% weight) and *Symbolism* (75% weight). Each node corresponds to a single artifact. The node shapes indicate ethnolinguistic groups: Slavic (circle), Finnic (hexagon), and Baltic (square). Shaded nodes designate archaeological instruments (10-13 cc.); the remaining nodes correspond to ethnographical instruments (17-20 cc.).

Such incongruence in similarity inference between the two perspectives suggests that the constructive principles of the psalteries were regionally constrained and possibly insured by master and apprentice relationship which has a strong linguistic component. Similarity in symbolic elements across cultures, however, appears to correspond more closely to the geographic proximity and, possibly, some symbolic features spread as decorative designs without affecting structural aspects of local musical instrument making traditions.

When both perspectives are analyzed simultaneously under equal weights, the resulting similarity graph is similar to those based on the analysis of physical attributes alone, but results in greater similarity amongst the Baltic

instruments (Figure 2C). This congruence between the two graphs can be accounted for by a much greater number of physical (80) than symbolic (20) attributes.

To reveal the impact of symbolic attributes given the situation that they were outnumbered by physical attributes, the data set was re-analyzed with 25% and 75% weights for the *Physical Attributes* and *Symbolism* perspectives respectively. The resulting similarity graph was identical to the results of the analysis under equal-weight with respect to the relationships among the Baltic, Finnic, and Slavic ethnographical instruments with two significant differences (Figure 2D). First, the relationships among the Baltic instruments were stronger (as five out of 6 instruments formed a single cluster). Second, the connection of most ancient, archaeological instruments shifted from the Baltic to the Finnic instruments.

The most comprehensive cladistic analysis of the Baltic psaltery failed to unequivocally resolve which of the three groups of instruments (Baltic, Finnic, or Slavic) were more closely related to the root of the tree, the medieval artifacts from Novgorod in northwestern Russia (Tëmkin & Eldredge, 2007). The recovery of the Lithuanian (Baltic) psaltery as most basal agrees with a presumed northward diffusion of the instrument (the second wave of dispersal) in (Tëmkin, 2004). The alternative scenario, in which the Novgorodian instruments bear greater similarity to the Finnic instruments (largely attested by shared symbolic significance) suggests an intriguing hypothesis for interpreting the instrument's history as it is more consistent with archaeological data which indicates that medieval Novgorod, where most ancient Baltic psalteries were discovered, had a substantial proportion of Finnic population (Tönurist, 1977).

## Discussion

By fusing physical information about artifacts with the conceptual information our ancestors were using to *create* these artifacts, we arrive at a more accurate picture of the evolutionary trajectories by which the artifacts evolved, and by which our human understanding of the world took shape. This paper develops the conceptual and mathematical foundation for a novel approach to reconstructing patterns of cultural evolutionary history based on graph theory. It uses algorithms for constructing and displaying similarity graphs that can be biased by conceptual knowledge from different domains. This approach circumvents the limitations of traditional phylogenetic approaches by (1) allowing for simultaneous analysis of cognitive information and physical character data, (2) providing the means for evaluating relative contributions of different types of data to historical inference, and (3) expanding hierarchical approach to include reticulate relationships.

We tested the utility of the conceptual network approach for inferring historical patterns of relatedness amongst artifacts by applying it the analysis of the Baltic psaltery, a stringed musical instrument unique to northwestern Europe. Not only did the approach capture the essential features of

the instrument's history inferred previously using other methods, it also provided new insights that invite a novel interpretation of the instrument's evolution. To achieve this, it was necessary to distinguish between hierarchically organized conceptual attributes (largely pertaining to sacred symbolic imagery), and physical characteristics (such as elements of the instrument's construction). Although this was readily accomplished with the current approach, it cannot be done with other approaches. The approach is not limited to a specific data types; it can be extended to include linguistic information, or any other discrete character information.

## Future Directions

Although limited in its present formulation, the conceptual network approach provides large number of avenues for future theoretical and mathematical developments. We are currently developing methods for computing the expected reliability of perspectives and determining the range of weights (parameter space) in which a given perspective becomes significant in the similarity computation. Other immediate plans include developing sophisticated software for analysis of the conceptual network.

In this investigation, we only explored the maximal similarity graph, which connects each artifact to the artifact that has the highest similarity to it according to the chosen perspective weight vector (first neighbours graph). In future investigations, we will consider the second or further most similar artifacts ( $n^{\text{th}}$  neighbour similarity graph), and establish a mechanism to automatically split the perspective space according to different criteria of similarity graph equivalence. This will enable us to explore the conglomeration of similarity graphs obtained from the different sets of perspective weight vectors. To further refine the approach, we will construct similarity graphs not only considering the most similar connections of each artifact, but connections above a certain threshold. This could reveal different similarity ranges where the parameter space is split in qualitatively different ways.

Finally, we plan to investigate the applicability of Kemp and Tenenbaum (2008) structure discovery models.

## Abstract

Earlier studies found a discrepancy between the display and feeling of surprise. Therefore, we assessed what factors influence the display of surprise in children of two age groups: 8- and 11-year-olds. We manipulated the social setting (children either competed or collaborated), and the cause of surprise (a surprisingly positive or negative event). We found that children used more features to express negatively caused surprise, compared to positively caused surprise and that 11-year-olds used more facial features than 8-year-olds. In a subsequent perception study, adults judged video clips with surprised and neutral reactions, for the degree of surprise that was displayed. We found higher ratings of surprise for negatively vs. positively surprised children, competing vs. collaborating children, and 11-year-olds vs. 8-year-olds. These results confirm that in addition to the feeling of surprise, its cause, the social setting, and age also affect the display of surprise.

**Keywords:** Emotions; facial expression; surprise; collaboration; competition; social development.

## Introduction

According to Ekman (1997), surprise is prototypically displayed through a combination of three facial features: people who are surprised raise their eyebrows, open their mouth and widen their eyes. However, when researchers try to elicit the expression of surprise with participants, this prototypical display is rarely shown (e.g., Reisenzein, Bördgen, Holtbernd & Matz, 2006). There appears to be a low emotion-facial display ratio, which means that when participants indicate they feel surprised, they do not frequently use the complete set of Ekman's features to express their emotion. We focus on two possible reasons for this.

First, earlier research often assumes that there is only one sort of surprise (e.g., Scherer, Zentner, and Stern, 2004). However, some studies have shown that surprise can be differently expressed, depending on its cause (e.g., Shepperd & McNulty, 2002). For example, when someone is surprised by a positive event, like giving an unexpectedly correct answer to a difficult question, his or her facial expression would differ from the facial expression of someone who is surprised by a negative event, like giving an unexpectedly incorrect answer to an easy question. This could be a reason for not finding a general full facial expression of surprise. Therefore, in our studies, we look at

different causes of surprise and its accompanying facial expressions.

Second, there may be contextual effects as well, in the sense that the expression of surprise could depend on the setting in which it is elicited, something which is often ignored in earlier studies. Research on surprise usually takes place in a nonsocial situation, sometimes even deliberately, to get a "clean" view on the expression of surprise (Reisenzein et al., 2006). However, we think that the social setting might be an important indicator for the expression of surprise. People tend to exaggerate, minimize, neutralize and fake expressions, depending on the social situation they are in (Matsumoto, Hee Yoo, Hiramaya & Petrova, 2005). For example, people probably express their surprise about an incorrect answer differently in the company of a teammate than in the company of an opponent. Such social factors may represent a second reason for a low emotion-facial display ratio. Hence, in this research, we examine the possible effect of the social situation on the facial expression of surprise more closely. We created a quiz game that could be played in two conditions, namely a collaborative or competitive setting. In this way, the participants' goals and interests varied in each condition and thus a different social context was created.

Adjusting behaviour and expressions to a social context is something people learn gradually. Children need time to acquire the social display rules, which means that younger children are not as skilled in that respect, compared to older children (Piaget, 1950). Earlier studies on children and surprise involved mainly perception and understanding of the emotion based on the theory of mind (e.g., Hadwin & Perner, 1991); they rarely concerned children's expression of surprise. Research that did study at children's expression of surprise involved merely infant participants (e.g., Scherer, Zentner, and Stern, 2004). We think it is important to study the expressions of surprise with older, more socially skilled, age groups as well. Saarni (1979) showed that children's adjusting behavior to social contexts doubles between the ages of 8 and 11. Therefore, we included both age groups (8 and 11 years old) in our studies.

In sum: the aim of this research is to study children's expressions of surprise, caused by different events (positive and negative events), in different social situations. To assess the influence of social setting and age on facial expressions of different sorts of surprise, we conducted three studies. The aim of the first study was to examine whether

participants actually experienced the different kinds of surprise differently. In our second study, we wanted to know whether features of the full facial display of surprise appeared, and whether there was an effect of age and social setting. In our third study, we focused on the perception of the facial expressions of surprise.

### Study 1: Production of surprise

We wanted to elicit different kinds of surprise using a natural elicitation procedure. Therefore, we created a game-based experiment in which two participants simultaneously had to play a knowledge quiz. In this quiz, we manipulated various questions to induce situations in which a quiz partner's answer was unexpectedly correct, or unexpectedly incorrect, in order to elicit either a surprised feeling with a positive cause, or a surprised feeling with a negative cause.

### Method

**Participants.** In total, 90 children participated in this study. We selected participants from two age groups; 8-year-old children (42 children in total, 45% girls) and 11-year-old children (48 children in total, 56% girls). The participants had to play a knowledge quiz in self-selected pairs. These pairs were randomly divided across two experimental conditions; half of the pairs played the game in a competitive setting and half of them in a collaborative setting. The experiment was conducted in two primary schools in Zoetermeer, the Netherlands. Beforehand, we informed parents about the experiment and asked for their signed permission for their child to participate.

**Stimuli.** The knowledge quiz consisted of 30 questions, which participants had to answer by taking turns, such that each of them responded to 15 questions. Both participants saw a question on their respective screens, but only one participant had to give an answer, while the other just listened to the response. For the next question in the list, they changed roles so that the other participant would answer a question, and vice versa. These questions were selected from the children's edition of the game *Triviant Pursuit* and a Dutch version of the "Wechsler Intelligence Scale for Children". We made sure that both easy and hard questions were included, in order to elicit both correct and incorrect answers. An example of an easy question is "Which month follows March?", an example of a difficult question is "What is glass made of?"

The participants were asked to sit behind two separate computer screens, which were arranged in such a way that they were not able to see each other or each other's computer screen (see Figure 1), but they were able to hear each other's answers. Participants were led to believe that they both saw the same list of questions on their computer screens. However, unknown to the participants, in order to elicit a surprise reaction, the questions posed were different for the two participants. In doing so, we could manipulate various questions to create situations in which the speaking participant's answer was unexpectedly correct, or

unexpectedly incorrect, according to the knowledge of the listening participant. More specifically, we aimed to elicit reactions of two types of surprise.

Figure 1. *Experimental setting*

First, we manipulated questions in such a way that participants were positively surprised. We showed the answering participant a question that was easy to answer, while the listening participant saw a question that was extremely difficult to answer. For example, the answering participant was given the question: "Which year follows 1933?", a question that is likely to be very easy to answer. However, simultaneously, the listening participant saw the question: "In which year was the city Tilburg established?" which is a difficult question. So to the listening participant, it would probably come as a positive surprise that his/her partner would give a quick and confident sounding response to this complex question.

Second, we also tried to elicit what we call surprise with a negative cause. We showed an easy question to both answering and listening participants, but these questions were not similar. For example, the answering participant was given the question: "Which animals live on a farm and roll in the mud?" while the listening participant saw the question: "Which animals live in an aquarium?" So to the listening participant, it would probably come as a negative surprise that his/her partner would give an incorrect answer to a relatively easy question.

For each pair of participants, we manipulated four questions to elicit surprise with a positive cause, and four questions to elicit surprise with a negative cause. This means that each participant answered two positively manipulated questions and two negatively manipulated questions, and listened to two positively manipulated answers and two negatively manipulated answers.

**Procedure.** Before the start of the quiz game, the pairs of participants were randomly assigned to a competitive or collaborative condition. Participants were told that they were going to play a knowledge quiz together and that they had to take turn in answering the questions that appeared on a screen. They were told to answer as many questions correctly as possible together (collaborative setting), or that they were playing against each other, and that they had to

compete to get the most correct answers (competitive setting). To emphasize this social setting, participants wore same colored T-shirts in the collaborative setting, and T-shirts with different colors in the competitive setting. Apart from the color of the T-shirts and the introduction given by the experimenter, the procedure was exactly the same for both conditions.

The participants' face and upper body were filmed by a video camera. After each answer, both participants had to indicate how certain they were about its correctness. In this way, we could see whether children indeed thought that the answers given by their opponent or team member were correct or incorrect, and check whether our manipulations worked properly. Participants had to indicate this certainty of correctness on a five-point Likert scale, by pointing out specific facial representations of the items to the camera. For example, a very unhappy face (corners of the mouth pulled down) represented a score of 1 (very uncertain about the correctness), and a very happy face (corners of the mouth pulled up) represented a score of 5 (very certain about the correctness). These facial representations of Likert scales are fairly standard for studies involving children (e.g., Lockl & Schneider, 2002) and our participants acknowledged that they are easy to use.

All pairs of participants began the experiment with a training part to ensure they were familiar with the quiz and the social setting they were in. This training phase consisted of ten questions with different levels of difficulty (five for each participant, without using any manipulations). To stimulate participants to try their best and to emphasize the social setting pairs were in (competition or collaboration), they were told that (depending on the condition) the best individual or the best team of the class would receive a prize. In addition, after participating in the experiment, all participants received a pencil and eraser as appreciation for their contribution.

## Results

We first checked whether our manipulations to elicit different types of surprise had worked by computing a difference score from the certainty scores of both answer-giving and listening participants. We expected these difference scores to diverge, in such a way that with a negative manipulation, the answering participant was sure that his/her answer was correct, and the listening participant was sure the answer was incorrect. For positive manipulations, we expected the answering participant to believe that his/her answer was correct, and the listening participant not to know the correct answer, which means that the listening participants would have to be less certain about the correctness. In the baseline condition, we expected both participants' certainty scores to be approximately the same.

We used analysis of variance (ANOVA) with the surprise manipulation (baseline, positive manipulation and negative manipulation) as between-subjects factor and the difference score as dependent variable. As shown in figure

2, there is an effect of the surprise manipulation, as reflected in the differences between speaker's and listener's certainty scores,  $F(2,43) = 80.101$ ,  $p < .001$ . A Bonferroni post hoc test showed that for the baseline condition ( $M = 0.22$ ,  $SD = 0.77$ ), the difference in speaker and listener's certainty score is significantly smaller, than with both the surprise manipulations. Moreover, the difference score for positive manipulations ( $M = 1.60$ ,  $SD = 1.12$ ) is in turn significantly smaller than for negative manipulations ( $M = 3.07$ ,  $SD = 1.32$ ).

Figure 2. Differences in certainty scores for surprise manipulations.

## Discussion

While participants played a knowledge quiz in pairs, we tried to elicit expressions of surprise by manipulating the situation in which a partner's answer would be unexpectedly correct or unexpectedly incorrect. From comparing the certainty scores for both manipulated questions and regular questions, we can presume that the manipulations generated situations that differed regarding the experienced degree of surprise. For negative manipulations, there was a large difference in certainty scores, positively caused surprise resulted in a smaller discrepancy between participants' certainty scores, and finally, certainty scores for baseline answers hardly differed from each other.

Next, we wanted to know whether the type of surprise had any effect on the facial expressions of the participants. Therefore, in the next part of this research, we investigate how children express the two differently caused emotions of surprise and whether this differs for the two age groups and social settings.

## Study 2: Expression of surprise

The aim of the second study is to gain insight into children's facial expression of surprise caused by different events. We investigate the presence of Ekman's full facial display of surprise in the data collected from our game based experiment.

## Method

**Stimuli.** We selected 96 video clips of children listening to the answer to a question by the other participant during the

quiz game, with an equal distribution of positively and negatively caused surprise manipulations and baseline condition (no manipulation), and with an equal distribution across age and social settings. This gave a 3 x 2 x 2 design (surprise x age group x social setting). We randomly selected three questions per couple for labelling purposes. For the positively caused surprise manipulation, we used all video clips with reactions to the answer to the “1933” question (in which the answering participant was given the question: “Which year follows 1933?”, a question that is very easy to answer. Simultaneously, the listening participant saw the question: “In which year was the city Tilburg established?” which is a difficult question) and for the negative surprise manipulation, we used the reactions to the answers to the “pigs in an aquarium” question (in which the answering participant was given the question: “Which animals live on a farm and roll in the mud?” while the listening participant saw the question: “Which animals live in an aquarium?”). As a baseline condition, we used the reactions to a third, easy, question without manipulation. For thirteen pairs the manipulation did not work properly, according to the comparison of the feeling of correctness scores of both participants, therefore we used data from 32 out of 45 pairs.

The selected video clips contained the listening participants’ reactions to the speaking participants’ answers, from the moment the question appeared on the screen until the next question was shown. For the purpose of labeling, all certainty scores presented by the children on the smileys were blurred and the video clips were presented without any sound.

Figure 3. Stills illustrating the three labeled features (left: eyebrow movement, middle: eye widening and right: mouth opening)

**Labeling and annotation.** Two independent labellers, who were blind for experimental condition (age, manipulation and social setting), manually coded all selected clips of listening children. Following an explicit procedure, they labeled the presence or absence of the features that represent the full facial display of surprise. According to Ekman (1997), this full facial display of surprise consists of three features: 1) moving the eyebrows, 2) dropping jaw or opening the mouth and 3) widening the eyes. For representative examples of the labeled features, see figure 3. Before labeling, coders had a short training phase, to make sure both coders labeled the video clips in the same way. All Kappa’s indicated acceptable inter coder agreement (Kappa’s were .64 for brow movements, .70 for eye opening

and .69 for mouth opening). Inconsistent labels were discussed until consensus was reached.

## Results

We used an ANOVA for analyzing the appearance of features belonging to Ekman’s (1997) full facial display of surprise in the video clips, with our surprise manipulations, age and social settings as between subject factors. Analysis of the full facial display of surprise (by counting up scores of separate features) shows an effect of the sort of surprise,  $F(2,96) = 27.836$ ,  $p < .001$ . A posthoc test (Bonferroni method) reveals a significant difference in the appearance of the full facial display of surprise between all three conditions (Baseline:  $M = .19$ ,  $SD = .134$ ; Positive manipulation:  $M = 1.00$ ,  $SD = .134$ ; Negative manipulation:  $M = 1.59$ ,  $SD = .134$ ).

When we take a closer look at the features, they all appear to be affected by the surprise manipulation. Table 1 shows that both brow movement and mouth opening are significantly more present in manipulated conditions than in the baseline condition, while a similar trend can be observed for eye widening.

Table 1. Percentages of appearance features in baseline condition, positive and negative manipulations.

	Baseline	Positive	Negative	Chi <sup>2</sup>
Brow movement	6.2%	40.6%	68.8%	$p < .001$
Eye widening	6.2%	21.8%	28.1%	$p = .069$
Mouth opening	6.2%	37.5%	62.5%	$p < .001$

We also found an effect of age on the overall appearance of the facial display of surprise,  $F(1,96) = 5.255$ ,  $p < .05$ . Older children ( $M = 1.10$ ,  $SD = .109$ ) use more features to express their surprise than younger children ( $M = .75$ ,  $SD = .109$ ). We found no effect of social setting on the overall appearance of the facial display of surprise,  $F(1,96) = .017$ , *ns*.

## Discussion

We found a significant difference in the frequency of use of the facial features between the three conditions. Participants who were surprised by a negative cause showed most facial features, compared with the other conditions. A closer look at the features reveals that mainly opening of the mouth and brow movement are used more with negatively caused surprise than with positively caused surprise. It seems that there is no difference in the features that are used in our created sorts of surprise, although there is difference in their relative frequency. We also found that older children used more features for showing surprise. An explanation for this could be that 11-year-old children show more surprise because they are more aware of the social situation (Saarni, 1979). We did not find a significant difference between the social settings. However, it is conceivable that the social

setting is important for expressing surprise, since *perception* of surprise is important for the function of self-presentation in a social setting. According to Feldman Barrett, Mesquita and Gendron (2011), facial features might carry affective information, but emotional meaning is rather contingent on context. Therefore, we decided to conduct a perception test using the same video clips as in study 2.

### Study 3: Perception of surprise

The third study consisted of a rating experiment to test how video clips from study 2 are perceived in terms of different sorts of surprise as a function of social setting and age group.

#### Method

**Participants:** Thirty students from Tilburg University (16 female) participated as judges in the perception experiment (age range: 18- 48 years old,  $M = 22.07$ ,  $SD = 5.42$ ).

**Stimuli:** The same 96 video clips that were labeled for the presence or absence of surprise features in study 2 were used in the perception test as stimuli.

**Procedure:** All 96 video clips were shown to the participants in one of two random orders. First, the identification number of the stimulus was presented (1 through 96), followed by the actual stimulus. During an inter-stimulus interval of three seconds the screen turned black, and participants were asked to rate the child's level of surprise, on a five-point Likert scale. To ensure that participants were familiar with the perception task, the experiment was preceded by a short training phase.

#### Results

We conducted a  $3 \times 2 \times 2$  ANOVA with sort of surprise, age and social setting as within-subject factors and the perceived level of surprise as dependent variable.

We found a main effect of social setting on the perceived level of surprise,  $F(1,29) = 72.023$ ,  $p < .001$ . Competing children ( $M = 3.93$ ,  $SD = 0.48$ ) were rated as more surprised than collaborating children ( $M = 3.48$ ,  $SD = 0.51$ ). Age did not have an effect on the perceived surprise level,  $F(1,29) = 3.494$ ,  $ns$ .

We also found an effect of sort of surprise on the perceived level of surprise,  $F(2,28) = 132.9$ ,  $p < .001$ . A Bonferroni post hoc test showed that children in the baseline condition ( $M = 3.01$ ,  $SD = 0.54$ ) were perceived to be less surprised than the children in both surprise manipulation conditions. Children with a negatively caused surprise ( $M = 4.54$ ,  $SD = 0.64$ ) were perceived to be more surprised than children with a positively caused surprise ( $M = 3.57$ ,  $SD = 0.64$ ).

We found two interaction effects involving sort of surprise. First, there is an interaction between age and sort of surprise,  $F(2,28) = 43.476$ ,  $p < .001$ . After running split analyses, were we looked at the perception of surprise for both age groups separately, we did not find a significant

difference in perceived surprise for the 8-year-old children between the baseline condition and the positive manipulation, but only a difference between these two conditions and the negative manipulation. For the perceived surprise of 11-year-old children there was a significant difference between all three conditions, see figure 4.

Figure 4. The interaction effect between age and type of surprise, on perceived level of surprise.

Second, we found an interaction effect between social setting and type of surprise on the perceived level of surprise,  $F(2,28) = 26.190$ ,  $p < .001$ . Post hoc analyses (Bonferroni method) reveal that in collaboration, there is a larger difference between the perception of positive and negative surprise than in competition. In the competitive setting, children are, overall, perceived to be more surprised than in the collaborative setting, see figure 5.

Figure 5. The interaction effect between social setting and type of surprise, on perceived level of surprise.

#### Discussion

The perception test showed that surprise was perceived differently between the three types of surprise. We found that positive surprise was perceived as less prominent than negative surprise. Furthermore, we found that 11-year-old children's expressions of surprise were perceived to be more distinct among the different conditions. This could mean that children express their surprise more accurately as they grow older. We also found that competing children are perceived to show more surprise than collaborating children, at least for the baseline condition and positive caused surprise.

## General discussion and conclusion

Earlier research has had difficulties in extracting a full facial display of surprise with participants (Reisenzein et al., 2006). The aim of the studies presented in the current paper was to examine two possible reasons for this; firstly the false assumption that there is only one kind of surprise and secondly the lack of taking contextual factors into account.

First, we assumed that surprise could be expressed differently, depending on its cause. We manipulated various questions in the knowledge quiz to extract reactions of surprise, either with a positive or negative cause. Analyzing the difference scores of participants' certainty judgments showed that the manipulations worked as intended (study 1). After annotating the facial features (study 2) and conducting a perception test (study 3), we can conclude that we found significant differences in expressing and perceiving surprise. Participants who were surprised by a negative cause showed most features of the full facial display of surprise, compared to the other conditions. Although we did find that manipulation affected the frequency in use of features, the different kinds of surprise were not related to certain specific features. It seems that the cause of the emotion leads to different *degrees* in surprise expressions, instead of a *different* surprise expression. Possibly, negative events cause more surprise than positive events. We must note, however, that the created social settings may have interfered with the concept of positive or negative surprise. For example, in competition, an incorrect answer on an easy question probably does not evoke an absolutely *negative* feeling of surprise with the opponent, as an error of the opponent is actually good for the other player. However, we still think that although the naming of the two kinds of surprise (positive versus negative) might be somewhat inaccurate, their difference in cause remains. In our research, we elicited feelings of surprise with two distinctive causes, and results show us that the cause of the surprise affects the expression of the emotion. However, future research should consider these causes in respect of the social settings participants are in.

Second, we wanted to study if the expression of surprise could depend on this social setting. Therefore, our participants played the knowledge quiz in either a collaborative setting, or a competitive setting. From study 3 we can conclude that children in competition were perceived to be more surprised than collaborating children. This may be due to the fact that children in competition are more aware of their social environment, because self-presentation is more important in this setting. Expressing surprise could be beneficial for the players' progression in the game. We can conclude that the social setting appears to be important for the expression of surprise.

Since 11-year-old children appear to adjust to social situations far more than 8-year-old children (Saarni, 1979), we also expected to find age to affect expressions of surprise. This was confirmed by our data analyses: 11-year-old children were more expressive and were perceived as more surprised than 8-year-old children. It seems that older

children can make a more accurate distinction between expressions of surprise with different causes than younger children.

We can conclude that the expression of surprise is affected by several factors, like age, social setting and the cause of the surprise. Therefore, we think future studies should consider these factors when studying surprise. Our data suggest that the expression of surprise is more than a mere reflex to an unexpected stimulus, and that it can be moderated by contextual factors.

## Acknowledgments

Many thanks to the children and teachers from third and sixth grade at primary schools Florence Nightingale and De Tjalk in Zoetermeer for their corporation. Thanks to Martijn Goudbeek and Marieke Hoetjes for their useful comments, and to Hans Westerbeek and Lisanne van Weelden for their assistance.

## Abstract

The constituents of English compounds (e.g., butter and fly for butterfly) and two-character Chinese words may differ in meaning from the whole word. Furthermore, the meanings of the words containing the same constituent (e.g., butter in “butterfingers”, or “buttermilk”) may or may not be consistent. Estimating semantic transparency of a constituent is usually difficult and subjective because of these uncertainties and ambiguities. It is rather unexplored why a constituent is considered transparent/opaque by raters, and how its polysemy correlates to its transparency. We propose a computational method for predicting semantic transparency based on Latent Semantic Analysis. We computed the primary meaning of a constituent by a clustering analysis and compared it to the whole-word meaning. The proposed method successfully predicted participants’ transparency ratings, and may explain the cognitive processes in raters when classifying semantic transparency of English compounds and two-character Chinese words.

**Keywords:** compound words; semantic transparency; latent semantic analysis; Chinese; clustering.

## Introduction

A compound word is a word composed of at least two free lexemes that refer to a new concept. Compound words with two constituents are defined as semantically transparent (transparent-transparent, referred to as TT, see Frisson, Niswander-Klement, & Pollatsek, 2008) when the whole word meaning can be grasped through its individual constituents, such as *cookbook*. Compound words are regarded as semantically opaque (opaque-opaque, OO), when their meaning cannot be fully derived from its constituents, e.g., *cocktail*. Some compound words are considered partially opaque (opaque-transparent, OT, or transparent-opaque, TO) when the primary meaning of one of the constituents is related to the meaning of the compound, such as *butterfly* or *staircase*, respectively.

Typically, transparency ratings are the most common method to obtain transparency information. Transparency rating experiments have used target words that differed substantially in their estimated transparency by researchers or a group of participants. For instance, Pollatsek and Hyönä (2005) selected 80 compound words, 40 of which they assumed to be semantically transparent, and the other 40 to be opaque. They asked eight participants to rate these words regarding their transparency using a 7-point scale (1 for

totally transparent and 7 for totally opaque), and the ratings were clearly lower for the supposedly transparent sets than for the supposedly opaque ones. Similarly, Frisson et al. (2008) asked 40 participants to rate transparency in terms of appropriate categories (e.g., opaque-transparent (OT), transparent-opaque (TO), opaque-opaque (OO), and transparent-transparent (TT)), and there was good agreement between the participants’ choices and the predefined classification by Frisson et al. (2008). The proportion of participants’ choices agreeing with the predefined classification was 65% for OO, 71% for OT, 65% for TO, and 86% for TT. Moreover, the proportion of participants classifying at least one of the constituents as opaque for the predefined opaque words was very high: 95% for OO, 93% for OT and 95% for TO. Inhoff et al. (2008) selected “headed” and “tailed” compound words, i.e., compound words whose meaning was primarily defined by their first or second constituents, respectively. They had 13 participants rate 390 compound words using an 11-point scale ranging from 0 to 10, where 0 indicated that the meaning of the compound was solely associated with the meaning of the first constituent, while 10 denoted that the meaning of the compound was solely associated with the one of the second constituent. Compounds with mean ratings below 4 (mean: 3.34) or above 6 (mean: 7.18) were considered to be headed or tailed, respectively. It is important to notice that the definition of headed and tailed compound words might not equal the TO and OT conditions discussed above. For example, the second constituent of a headed compound may be opaque or transparent, as long as its meaning is less closely related to the compound than the meaning of the first constituent is.

Two-character Chinese words, similar to English compound words, differ in how the meanings of the first and second characters relate to the meaning of the word. Some two-character Chinese words are semantically transparent, i.e., both characters are transparently related to the meaning of the whole word. Other words are fully opaque, i.e., the meaning of neither constituent is related to the meaning of the compound, or partially opaque. Table 1 lists some examples of transparent, opaque, and partially opaque Chinese words.

According to the estimation of Zhou and Marslen-Wilson (1995), 74% of Chinese words are made up of two characters, although some words consist of only one

character and some consist of three or more characters. A Chinese character is a writing unit which has a single syllable and meaning(s). It is approximately equal to a morpheme in most cases. However, unlike English and other alphabetic writing systems, Chinese words are written without spaces in a sequence of characters. The concept of a word is not as clearly defined in Chinese as it is in English, which means that Chinese readers might somewhat disagree where word boundaries are located (see Rayner, Li, & Pollatsek, 2007, for a review). According to the segmentation standard by Huang, Chen, Chen, and Chang (1997) used by the Academia Sinica Balanced Corpus (ASBC; Academia Sinica, 1998), not all characters constitute one-character words. Furthermore, a Chinese character might be shared by many words, but the meaning of the character and those words may not be consistent.

Table 1. Examples of transparent, opaque, and partially opaque Chinese words. The meaning of the whole word and the primary meanings of 1st and 2nd characters are shown in parentheses.

	Whole Word	1st Character	2nd Character
TT	球場 (ball court)	球 (ball)	場 (court)
OO	壽司 (sushi)	壽 (age)	司 (in charge of)
TO	智商 (I.Q.)	智 (Intelligent)	商 (commerce)
OT	開水 (boiled water)	開 (open)	水 (water)

Early studies of the morphological processing of Chinese polymorphemic words asked how compound words are represented in the mental lexicon and how their lexical processing in visual or auditory word recognition is performed. Recent studies investigated semantic composition (Mok, 2009) and frequency effects (see Zhou, Ye, Cheung, & Chen, 2009, for a review). In Mok (2009), the experimenter pre-defined semantic transparency on a 6-point scale, where 1 is opaque and 6 is transparent. A constituent was classified transparent if the rating was equal to or greater than 4, and opaque otherwise. Five participants were then provided the 6-point scale again for each constituent. Constituents with an average rating greater than 3.5 were classified as transparent, and the others were categorized as opaque.

There are also a few unpublished studies attempting to estimate semantic transparency of Chinese two-character words by researchers or human raters such as Tsai (1994), Lee, C. Y. (1995), and Lee, P. J. (2007). For example, a five-point scale ranging from 1 to 5 was used in the study by Lee (2007), and words were considered transparent when the average score was below 2 while opaque when the average score was greater than 4. Tsai (1994) categorized opaque words into OT and TO conditions, but Lee (1995) and Lee (2007) generalized OT, TO, or OO conditions as opaque words (referred to as idiomatic words).

Unfortunately, estimates of semantic transparency are often subjective and vary across raters, and sometimes even

the meaning of transparent compounds cannot be unambiguously determined from the meanings of their constituents (see Frisson et al., 2008). Inhoff et al. (2008) pointed out that a semantic relationship often exists between an opaque lexeme and its compound, for example, even though “jailbird” typically refers to a person rather than an animal, it can convey useful semantic information, such as being caged or wishing to fly free. This topic was also studied in the literature on conceptual combination (e.g., Wisniewski, 1996; Costello & Keane, 2000), which indicated that one part of a compound has an *exocentric interpretation* such as *shape* (“seahorse” is a fish whose head is the *shape* of a horse’s head) or the head concept (in the “seahorse” case the diagnostic predicate being *shape*). Participants might be able to interpret constituents being defined as opaque to a meaning related to the compound according to some kinds of relation (e.g., *shape*) or the polysemy of the constituent and compound. This subjectivity and variability also occurs in characters of Chinese two-character words. Therefore, a computational model may be a way to average across subjective differences of estimating semantic transparency.

## Predicting Transparency using Latent Semantic Analysis

This study proposes a computational method for estimating transparency using Latent Semantic Analysis (LSA). LSA is a method to represent the meaning of words by statistical computations applied to a text corpus (Landauer & Dumais, 1997; Landauer, McNamara, Dennis, & Kintsch, 2007). Typically, terms are words, and a term-to-document co-occurrence matrix is established from a corpus. Then a mathematical method, singular value decomposition (SVD), is used to reduce the dimensions of the original matrix (see Martin & Berry, 2007). The meaning of each term is represented as a vector in *semantic space*. One can compute the semantic similarity values for any two terms in a given language using the LSA cosine value, which ranges between -1 and 1, but rarely goes below 0. Randomly chosen pairs of words have a mean of 0.03 and a standard deviation of approximately 0.08 (see Landauer et al., 2007). An LSA web site is freely available (<http://lsa.colorado.edu/>, accessed September, 2010; see Dennis, 2007).

LSA has been successful at simulating judgments of semantic similarity, word categorization, discourse comprehension, essay quality (see Landauer & Dumais, 1997; Landauer et al., 2007; Jones & Mewhort, 2007, for a review). LSA has also been used to investigate morphological decomposition; for example, Rastle, Davis, Marslen-Wilson and Tyler (2000) investigated morphologically complex words with semantically transparent embedded stems (e.g., “depart” vs. “departure”) and opaque embedded stems (e.g., “apart” vs. “apartment”). Furthermore, Diependaele, Dunabeitia, Morris and Keuleers

(2011) used LSA to estimate transparency between full words and constituent-embedded stems, which yields “viewer” vs. “view” as being highly transparent and “corner” vs. “corn” as highly opaque.

One possible method (abbreviated as C2W) of measuring semantic transparency is, similar to Diependaele et al. (2011), to compute the LSA cosine values between the compound word and each of its constituents. For example, the LSA cosine value between “staircase” and “stair” is 0.57 while the one between “staircase” and “case” is 0.07. Since the constituent “stair” and the compound word “staircase” result in a clearly higher cosine value, “stair” is considered semantically transparent, while “case” is considered opaque. However, this computation for English words may or may not reflect how a Chinese rater classifies a constituent as transparent/opaque for two-character Chinese words.

One possible solution is to access the primary meaning of a constituent. The first step of our proposed idea is to find words containing a constituent that a rater possibly activates. Since a constituent may have several meanings, the *primary meaning* of the constituent is computed by a hierarchical clustering algorithm. Since LSA cosine values rarely go below 0 in high-dimensional spaces, we use one minus the absolute value of the LSA cosine as distance function and a given threshold. The selection of this threshold is discussed below in the Reanalysis of Previous Data and General Discussion sections. Since word frequency is important for word recognition and reading (see Rayner et al., 2007), the cluster with the highest sum of word frequency is considered the primary meaning. For example, the transparency of constituent “butter” in “butterfly” is determined as follows. Using the text corpus “general reading up to 1<sup>st</sup> year college,” the LSA cosine values among “butter”, “butterfly”, “buttercup”, “butterfingers”, “buttermilk”, “butterscotch”, “butterfat”, and “butterwick” are shown in Table 2. Based on the LSA cosine values, semantic relationships can be visualized by multi-dimensional scaling (MDS) as presented in Figure 1. The results of the cluster analysis are demonstrated in Figure 2. The group of “butter”, “buttercup”, “buttermilk”, “butterscotch”, “butterfat”, and “butterwick” are considered primary meaning for their highest sum of frequency. According to a threshold 0.9, “butterfly” and “butterfingers” are clustered individually. We applied “document to term” comparison to compute the LSA cosine value between the primary meaning cluster (i. e., a string of “butter buttercup buttermilk butterscotch butterfat butterwick”) and “butterfly”, and 0.04 is obtained. This approach is abbreviated as M2W.

The M2W approach takes the polysemy of a constituent into account and works even when a constituent is not a stand-alone word. M2W is especially useful for the Chinese language in which many characters do not exist as one-character words in the corpus (described below).

Since the LSA-based method may be able to estimate transparency of English compounds, it could possibly be applied to Chinese two-character words in a similar manner.

Table 2. The LSA cosine values among “butter”, “butterfly”, “buttercup”, “butterfingers”, “buttermilk”, “butterscotch”, “butterfat”, and “butterwick”.

butter	-fly	-cup	-fingers	-milk	-scotch	-fat	-wick

Figure 1: The MDS result for an example of semantic relationships for “butter” and words containing “butter”. The frequency for each word in British National Corpus (BNC) is shown in parentheses. The x and y axis represent dimensions 1 and 2, respectively, of the abstract, two-dimensional Euclidean output space of the MDS algorithm.

Figure 2. The results of hierarchical clustering of the example word “butter”.

Following the principle of creating semantic spaces (Quesada, 2007), our previous studies (Wang et al., 2010; Chen, Wang, & Ko, 2009) built an LSA semantic space of Chinese (abbreviated as SP-C) from ASBC which contains approximately 5 million words (or 7.6 million characters). Texts in ASBC were collected from different topic areas and classified using five criteria: genre, style, mode, topic, and source, in order to make ASBC a representative sample of modern Chinese language. Word segmentation was performed manually according to the standard by Huang et al. (1997). For representatives of words in the corpus, words that occurred less than 3 times per 5 million were excluded. A 49021 x 40463 term-to-document co-occurrence matrix was then established. SP-C has been shown to successfully estimate word predictability (see Wang et al., 2010) and word association in Chinese language (see Chen, Wang, & Ko, 2009).

The term-to-document co-occurrence matrix of SP-C was established using the unit of words, which may be one or more Chinese characters. The C2W approach requires Chinese two-character words to have their constituent characters appear as single-character words more than 3 times in the corpus. Within the 49021 words available in SP-C, 31,637 are two-character words. For 3,921 out of these 31,637 two-character words, either the first or second characters are unavailable due to the frequency restriction. Nevertheless, the M2W approach can still compute the primary meaning of characters despite this characteristic of Chinese. It is even possible that a Chinese reader does not have a single-character representation in his or her mental lexicon for non-stand-alone characters. The polysemy of a character might be involved and the primary meaning might be obtained during lexical access.

Table 2 shows examples of the polysemy of character “馬” (horse). The whole-word meanings of words such as “馬背” (horse back) and “馬鞍” (saddle) are close to “馬” (horse), while the ones of words, e.g., “馬虎” (careless) and “馬桶” (stool) are not. The character “馬” in the word “馬來” (Malaysian, pronunciation: ma-lai) and “馬國” (Malaysia) refers to the abbreviation of Malaysia/Malaysian because of its pronunciation. Figure 3 demonstrates the clustering of character “馬” - the meaning of “馬” is “horse” in words 1 to 4, and is related to “Malaysia” in words 8 and 9. Since the sum of frequency in ASBC for the group of words 1 to 4 is the highest, the group of words 1 to 4 is considered the primary meaning of character “馬”.

It is necessary to verify the proposed computational method by comparing its results with human transparency ratings. We evaluated how LSA estimates transparency of English compounds using the materials of Frisson et al. (2008). The evaluation for two-character Chinese words was conducted by re-analyzing the materials of Tsai (1994) and Lee (2007).

Table 2. A list of character “馬” as one-character word and the two-character words beginning with character “馬”. C2 Meaning is the primary meaning of the second character. WFreq is whole-word frequency in ASBC.

	Word	Whole-Word Meaning	C2 Meaning	WFreq
1	馬	horse		342
2	馬背	horse back	back	14
3	馬鞍	saddle	saddle	4
4	馬車	carriage	car	37
5	馬虎	careless	tiger	13
6	馬桶	stool	tub	23
7	馬腳	a clue of	foot	4
8	馬來	Malaysian	come	11
9	馬國	Malaysia	country	12

Figure 3. The results of hierarchical clustering of example “馬” with numbers referring to Table 2.

## Reanalysis of Previous Data

Ten opaque-opaque, 14 opaque-transparent, and 10 transparent-opaque compounds defined in Frisson et al. (2008) were estimated by our classifiers using C2W and M2W. A receiver operating characteristic (ROC) analysis was performed and the area under the curve (AUC) was used as measurement. Figure 4 illustrates the ROC curves for C2W and M2W (threshold = 0.1, 0.8, and 1), and the AUCs are 0.82, 0.74, 0.82, and 0.75, respectively. A threshold too low may generate too many groups, while a threshold too high only produces one group and therefore causes more false alarm cases. We found that when a compound is high-frequent and its constituent is opaque and low-frequent, the primary meaning of the constituent might be taken over by the compound and therefore the constituent is incorrectly considered transparent. We suggest that C2W could be used when the constituent is low-frequent, and an item-level human judgment should be performed for further analysis.

Figure 4: ROC curves for C2W and M2W (threshold = 0.1, 0.8, and 1) for English readers.

For two-character Chinese words, we pre-defined 160 characters selected from the materials of Tsai (1994), Lee, C. Y. (1995), and Lee, P. J. (2007) as either transparent (T) or opaque (O), then those characters were rated by eleven students who completed a college degree in Taiwan participated. All participants were native speakers of Chinese (traditional script). Participants were presented with the two-character word, and asked to respond either “T” or “O” for each constituent. The measure of human rating of each constituent was calculated as the probability with which participants responded “T” to the constituent, e.g., 0.91 for 10 out 11 participants responding “T.” The means and standard deviations of human rating (Human), C2W, and M2W are shown in Table 3, where there are 99 transparent and 50 opaque constituents available for C2W. Figure 5 illustrates the results of the ROC analysis, and the AUCs of human rating, C2W, and M2W are 0.99, 0.76, and 0.85, respectively. The Spearman rank correlations (a non-parametric test) between Human and C2W and between Human and M2W are 0.48 and 0.53, respectively. These results suggest that M2W not only overcomes the constraint that C2W is unable to compute transparency when constituents are unavailable in SP-C, but also outperforms C2W in ROC and correlation analyses. As mentioned above, the concept of a word is not as clearly defined in Chinese as in English, and Chinese readers might learn the polysemy of characters implicitly from polymorphemic words. We suggest that M2W may be a better approach than C2W for predicting transparency of constituents of two-character Chinese words.

Table 3. The means and standard deviations (in parentheses) of human rating (Human), C2W, and M2W.

	Human	C2W	M2W
T	0.79 (0.19)	0.22 (0.17)	0.35 (0.27)
O	0.13 (0.14)	0.08 (0.06)	0.07 (0.10)

Figure 5: ROC curves for human rating (Human), C2W and M2W for Chinese readers.

## General Discussion

The most important outcome of the current study is its proposed computational method of using LSA to estimate semantic transparency, which may reflect the polysemy of constituents and how raters access meanings. Corroborating evidence from two different languages was presented by testing the method with English compounds used in prior compound word study (including Frisson et al., 2008) and two-character Chinese words in the transparency judgment in this study.

The results could be adapted to further Chinese reading research using eye movements. For example, it is still being debated how Chinese words are accessed by readers. Yan, Tian, Bai, and Rayner (2006) investigated the effect of word and character frequency on word processing, and they suggested that when a two-character word is frequent and has been seen quite often in print, it is accessed as a single entity in the mental lexicon of Chinese readers, whereas when it is infrequent, the word needs to be accessed via its characters (and hence an effect of character frequency emerges). However, some studies have argued for the priority of characters over words (e.g., Chen, Song, Lau, Wong, & Tang, 2003). Therefore, it is still unclear how opaque and transparent words are processed during natural reading. It would be valuable to address these issues using semantic transparency and eye-movement analysis.

The current limitations of the proposed method in Chinese might be the relatively small corpus size. Cai and Brysbaert (2010) published SUBTLEX-CH based on a larger corpus (47 million characters) of film and television subtitles, and they suggested that SUBTLEX-CH is a good estimate of daily language exposure and captures much of the variance in word processing efficiency. It is possible that a Chinese LSA semantic space could be established based on this larger corpus as long as the corpus provides enough information in terms of “documents”, i.e., a set of words that relate to the same topic in a document. It is important to

notice that the size of a corpus is not its only criterion of being representative, but the selection of texts covering different varieties in a corpus should also be taken into account. Furthermore, there are traditional and simplified scripts of Chinese, and it is important to test whether the semantic space built by traditional Chinese is compatible with simplified Chinese.

In addition to the selection of the threshold, since it is related to the distance function of the clustering algorithm and the LSA values, we suggest that an optimization test should be performed for each semantic space. We imply that a threshold might be involved in the transparency judgments by human raters and that each participant might have a different threshold for the “cut-off” of opacity. It should be clear that the use of the proposed computational method is not intended to replace the standard measures that are based on human raters, but that it offers a different perspective and an opportunity to examine the lexical processing for estimating semantic transparency.

## Acknowledgments

Portions of the data were presented at the Asia-Pacific Conference on Vision (APCV) 2010. Thanks to Keith Rayner, Jinmian Yang, and Marc Brysbaert for helpful comments on this study.

## Abstract

Previous studies have found that viewers' attention is disproportionately attracted by texts, and one possible reason is that viewers have developed a "text detector" in their visual system to bias their attention toward text features. To verify this hypothesis, we add a text detector module to a visual attention model and test if the inclusion increases the model's ability to predict eye fixation positions, particularly in scenes without any text. A model including text detector, saliency, and center bias is found to predict viewers' eye fixations better than the same model without text detector, even in text-absent images. Furthermore, adding the text detector – which was designed for English texts – improves the prediction of both English- and Chinese-speaking viewers' attention but with a stronger effect for English-speaking viewers. These results support the conclusion that, due to the viewers' everyday reading training, their attention in natural scenes is biased toward text features.

**Keywords:** real-world scenes; text detector; eye movements; visual attention.

## Introduction

When inspecting real-world scenes, human observers continually shift their gaze to retrieve information. Viewers' attention has been found to be biased toward visually salient locations, e.g., high-contrast areas, during scene viewing or search (Itti & Koch, 2001) or toward the center of the screen when viewing scenes on computer monitors (Tatler, 2007). Since it is also known that viewers pay a disproportionate amount of attention to faces (Cerf, Frady, & Koch, 2009), Judd, Ehinger, Durand, and Torralba (2009) equipped their model of visual saliency with a face detector (Viola & Jones, 2004) and a person detector (Felzenszwalb, McAllester, & Ramanan, 2008). In those images that contained depictions of people, their model with all features combined outperformed models trained on typical saliency features such as color, orientation, intensity, and contrast. Cerf et al. (2009) refined the "standard" saliency model by adding a channel of manually-defined regions of faces, texts, and cellphones, and demonstrated that the enhancement of the model significantly improved its ability to predict eye fixations in natural images.

Besides depictions of people, texts in natural scenes are usually important pieces of information, which could be shown on depictions of signs, banners, advertisement billboards, license plates, and other objects. Human text

detection in natural scenes is critically important for people to survive in everyday modern life, for example, by drawing attention to traffic signs or displays showing directions to a hospital or grocery store. Our previous studies (Wang & Pomplun, 2011; under revision) suggested that attention seems disproportionately attracted by texts but that the specific visual features of texts, e.g., edge density, rather than typically salient features such as color, orientation, intensity, or contrast, are the main attractors of attention. This finding was in line with the results in Baddeley and Tatler (2006) that high spatial frequency edges, not contrasts, predict where we fixate.

Automatic text detection has been a hot topic in the fields of computer vision and pattern recognition for its practical applications. The special features of texts, e.g., the small variation of the stroke width (see Epshtein, Ofek, & Wexler, 2010; Jung, Liu, & Kim, 2009) or edge density (Lu, submitted) have been used to develop text detectors. Although many text detection techniques, i.e., texture-based, region-based, and stroke-based methods, have been reported, many non-text objects, such as windows, fences, or brick walls, easily cause false alarms (see Lu, submitted; Ye, Jiao, Huang, & Yu, 2007, for a review). Furthermore, many established text detectors are restricted under commercial patents. Therefore, only few text detectors are freely available or have been tested in visual attention studies.

Lu, Wang, Lim, and Pomplun (submitted) developed specialized text features, e.g., histograms of edge width and edge density, trained with Support Vector Machine (SVM) classifiers. The study reported better performance compared with earlier studies (e.g., Epshtein, et al., 2010; Jung, et al., 2009) on public text-detecting competition datasets (ICDAR2003 and ICDAR2005). In the present study, we used the automatic text detector developed by Lu et al. (submitted) to test whether it can improve the prediction of viewers' fixations. This detector employs contrast of strokes over background, width of strokes, joints of horizontal and vertical strokes, and stroke structure as key variables

Although manually-defined regions of texts were shown to improve the prediction of eye fixations in text-present images (Cerf et al., 2009), it is unclear if viewers' attention is biased toward any non-text objects which share some features of texts, particularly in text-absent images. In the present study, two eye-movement datasets obtained in our previous investigations (Wang & Pomplun, under revision)

are re-analyzed. The goals of the present study are (1) to investigate the contribution of the automatic text detector to the prediction of eye fixations in real-world scenes, and (2) to verify the hypothesis that viewers' text detection skills are "trained" through exposure to language and affect attentional control even in text-absent scenes

## Experiment 1: Unconstrained Texts

We superimposed unconstrained texts onto real-world scenes, i.e., placed them in unexpected locations, in front of either homogeneous background, i.e., in regions with the lowest luminance contrast in the image before placing the text parts, or inhomogeneous background, i.e., those areas with the highest luminance contrast, and found that texts attracted more attention than non-text objects. This dataset is chosen for re-analysis in the present study since the stimuli contain both text-present and text-absent images. Two models, both including saliency and center-bias maps (channels), but one with and one without text-detector map are compared in order to determine whether the inclusion of the text detector improves the prediction of fixations, particularly in text-absent images.

## Method

**Participants.** Twelve students from the University of Massachusetts at Boston participated. All had normal or corrected-to-normal vision and were between 19 and 40 years old. Each participant received 10 dollars for a half-hour session.

**Apparatus.** Eye movements were recorded using an SR Research EyeLink Remote system with a sampling frequency of 1000 Hz. Subjects sat 65 cm from an LCD monitor approximately 34 x 25 degrees of visual angles. A chin rest was provided to minimize head movements. After calibration, the average error of visual angle in this system is 0.5°. Stimuli were presented on a 19-inch Dell P992 monitor with a refresh rate of 85 Hz and a screen resolution of 1024x768 pixels. Although viewing was binocular, eye movements were recorded from the right eye only.

**Stimuli.** Two hundred natural-scene images were selected from the LabelMe dataset (Russell, Torralba, Murphy & Freeman, 2008). Eighty out of these images were randomly selected to be superimposed with one text and one line drawing. The other 120 images were presented without any modification. For the placement of texts and line drawings, two different items (items A and B in Table 1) were chosen for each scene, and their addition to the scene was performed under four different conditions: either (1) a word describing item A (e.g., "sled" as shown in Table 1) and a drawing of item B, (2) a word describing item B (e.g., "yoyo") and a drawing of item A, (3) a scrambled version of a word describing item A (e.g., "dsle") and a drawing of item B, and (4) a scrambled version of a word describing item B (e.g., "yyoo") and a drawing of item A. All four conditions of text-drawing pairs were presented in a between-subject design, i.e., each participant only viewed one of these conditions. Half of the words (object labels)

were placed in front of homogeneous background and the other half were placed on inhomogeneous background. Figure 1 shows an example of all four conditions with words and drawings on homogeneous background. The eccentricity of the text or the drawing was randomly assigned and varied between 200 and 320 pixels (average: 253 pixels). The minimum polar angle, measured from the screen center, between the text and the drawing in each image was set to 60 degrees to avoid crowding of the artificial items. All texts and drawings were resized to cover approximately 2500 pixels.

Table 1: Examples of texts (words and scrambled words) and object drawings used in Experiment 1.

	Item A	Item B
Texts	sled (dsle)	yoyo (yyoo)
Object Drawing		

Figure 1. An example of 4 conditions of stimuli for low-frequency words drawn on homogeneous background. (a) Word of Item A (sled) vs. drawing of Item B, (b) word of Item B (yoyo) vs. drawing of Item A, (c) scrambled word of Item A (dsle) vs. drawing of Item B, and (d) scrambled word of Item B (yyoo) vs. drawing of Item A.

**Procedure.** Equal numbers of subjects freely viewed stimuli from conditions 1, 2, 3, and 4 in a counter-balanced design (described below), and each stimulus was presented for 5 seconds. The free viewing task has been widely used in previous studies (e.g., Judd et al, 2009; Cerf et al., 2009). The software "Eyetrack" developed by Jeffrey D. Kinsey, David J. Straczuzi, and Chuck Clifton, University of Massachusetts Amherst, was used for recording eye movements.

**Analysis.** Two eye movement measures were taken: *correlation (R)* and *Receiver Operating Characteristic (ROC)*. The Pearson correlation coefficient  $R$  between two maps is computed according to sampling points taken every 10 pixels along the  $x$  and  $y$  axes, and then the correlation coefficient between saliency/center-bias/text-detector and attentional maps (described below) are obtained. An example of a stimulus image and its attention, saliency, center-bias, and text-detector maps is shown in Figure 2. The computation of the ROC measure is described in Hwang, Higgins & Pomplun (2009). If a map had higher correlation or ROC values with regard to the subjects' fixations, the map was considered a better predictor of visual attention. The chance level is 0.5 for ROC and 0 for  $R$ .

Figure 2. An example of (a) stimulus image, (b) attention (3-second viewing) (c) saliency, (d) center-bias, and (e) text-detector maps.

Saliency was calculated by the freely available computer software “Saliency Map Algorithm” using the standard Itti, Koch, and Niebur (1998) saliency map based on color, intensity, orientation, and contrast. A center-bias map was obtained using a two-dimensional Gaussian distribution at the center of the screen with 3 degrees of visual angle (90 pixels in our experiment setting). The text-detector maps were computed using the automatic text detector which analyzes features such as variation of edge width and edge density.

For the attentional map, we excluded the initial center fixation and included all other fixations within a given viewing duration. The attentional map was built according to each fixation in an image by a two-dimensional Gaussian distribution centered at the fixation point, where the standard deviation was one degree of visual angle to approximate the size of the human fovea. Then we simply summed up these Gaussian distributions for fixations weighted by their durations (see Pomplun, Ritter, & Velichkovsky, 1996).

We computed the attentional maps for each image inspected by each viewer for the initial 1.5, 2, ..., 5 seconds.

The averages of correlations and ROC values for each viewer were calculated for all, text-present, text-absent, text in front of homogeneous (H-BG), and text in front of inhomogeneous backgrounds (INH-BG) images, and an ANOVA and paired t-tests were performed to analyze the differences between these values

## Results and Discussion

**Models with and without Text-Detector Maps.** The average  $R$  and ROC values of all 12 viewers are shown in Table 2. Text-detector maps overlap attentional maps the best when the images contain text in front of homogeneous background, and the worst in text-absent images. These results are consistent with the finding by Judd et al. (2009) that object detectors by themselves do not predict attention well when the objects are absent and therefore should be used in conjunction with other features.

Table 2: The average  $R$  and ROC of saliency (Sali), center-bias (Center), text-detector (TextDet), saliency combined with center-bias (SC), and all combined (SCT) maps as predictors of the attentional maps for 3-second viewing. H-BG represents images in front of homogeneous background, and INH-BG represents images on inhomogeneous background.

	Sali	Cen	TextDet	SC	SCT
R - All	0.14	0.16	0.15	0.18	0.20
Text-Present	0.11	0.12	0.20	0.14	0.16
H-BG	0.09	0.10	0.24	0.10	0.12
INH-BG	0.14	0.15	0.15	0.17	0.19
Text-Absent	0.15	0.19	0.12	0.21	0.22
ROC - All	0.65	0.63	0.63	0.69	0.72
Text-Present	0.61	0.61	0.66	0.64	0.70
H-BG	0.55	0.60	0.67	0.58	0.67
INH-BG	0.67	0.62	0.64	0.70	0.72
Text-Absent	0.67	0.64	0.62	0.72	0.73

One-way ANOVAs with the factor “predictor” showed that the performances of Sali, Cen, TextDet, SC, and SCT maps differed significantly in all, text-present, H-BG, INH-BG, and text-absent images for  $R$ , all  $F_s(4; 55) > 3.64$ ,  $ps < .05$ , and ROC, all  $F_s(4; 55) > 11.17$ ,  $ps < .01$ . SC (without text-detector) obtained significantly lower measures than SCT (with text-detector maps) for all, text-present, H-BG, INH-BG, and text-absent images for  $R$ , all  $t_s(11) > 3.93$ ,  $ps < .01$ , and ROC, all  $t_s(11) > 7.68$ ,  $ps < .001$ . The results indicate that the text detector improved the prediction of viewers' visual attention. It is interesting to see that the SCT obtained higher  $R$  and ROC than the SC even in text-absent images. One plausible explanation is that some non-objects containing text-like features catch a disproportionate amount of attention.

**Text-Present vs. Text-Absent and H-BG vs. INH-BG Images.** The five predictors were analyzed in one-way ANOVAs with the factor “image type,” and the results

demonstrate that both R and ROC values significantly differed in all, text-present, text-absent, H-BG, and INH-BG images, all  $F_s(4; 55) > 4.91$ ,  $p_s < .01$ , and all  $F_s(4; 55) > 4.72$ ,  $p_s < .01$ , respectively, except ROC for Cen,  $F(4; 55) = 0.92$ ,  $p > .4$ . The text detector (TextDet) performed better for text-present images than text-absent ones with regard to R,  $t(11) = 10.67$ ,  $p < .001$  as well as ROC,  $t(11) = 5.66$ ,  $p < .001$ . Homogeneous background images obtained higher values than inhomogeneous background images for both R,  $t(11) = 7.31$ ,  $p < .001$ , and ROC,  $t(11) = 3.94$ ,  $p < .01$ .

**Visual Attention over Time.** SCT outperformed SC (without text detector) for all viewing durations for R and ROC in both text-present images, both  $t_s(11) > 9.68$ ,  $p_s < .001$ , and text-absent ones, both  $t_s(11) > 3.93$ ,  $p_s < .01$ . The difference between SCT and SC was larger in text-present images than in text-absent ones. In text-present images, the R of TextDet initially dominated but decreased over time, while the R of Sali increased (see Figure 3a). These data suggest that texts are typically detected early during the inspection process and receive sustained attention while the viewers are reading them, thereby elevating the occurrence of text features near fixation. Later in the process, viewers tended to be guided more strongly by saliency as defined by the Itti and Koch algorithm. In text-absent images, the R of Sali, Cen, and TextDet increased over time, indicating that the corresponding mechanisms became more important during the later – likely more focused and fine-grained (Unema, Pannasch, Joos, & Velichkovsky, 2005) – stages of inspection. Clearly, Sali and Cen played more important roles when texts are absent.

Figure 3. Correlations for 1.5-, 2-, ..., and 5-second viewing of (a) text-present and (b) text-absent images.

## Experiment 2: English vs. Chinese Texts and Native Speakers

In Experiment 1, we showed that the addition of a text-detector map to saliency and center-bias maps makes the model a better predictor of viewers' visual attention. Our

hypothesis is that viewers have developed a “text detector” because they are exposed to texts everyday and become sensitive to text-patterns. Wang and Pomplun (under revision) found that native speakers of English and Chinese-speakers were both attracted by English and Chinese texts in real-world scenes but were attracted more strongly by the texts of their native languages. The reason might be that English and Chinese texts share some common features, such as the histogram of edge width, but also contain their unique features, e.g., Chinese texts usually contain vertical, horizontal, and diagonal strokes but fewer “curves” (such as in “O” or “G” in English). In Experiment 2, the dataset in Wang and Pomplun (submitted) was reanalyzed and our expectation was that the text detector (Lu, submitted) designed for English texts will perform better prediction of gaze fixations for English-speaking viewers than for Chinese-speaking ones.

## Method

**Participants.** In the group of non-Chinese English speakers, 14 students from the University of Massachusetts at Boston participated. All of them were native speakers of English, and none of them had learnt any Chinese or had participated in Experiment 1. For the group of Chinese speakers, 16 native speakers of Chinese were recruited at China Medical University, Taiwan. Each participant received 10 US dollars or 100 Taiwan dollars, respectively, for participation in a half-hour session. All had normal or corrected-to-normal vision.

**Apparatus.** At both sites, the experiment setup was identical to Experiment 1.

**Stimuli.** As shown in Figure 4, the original texts were either rotated by 180 degrees or replaced by Chinese texts. The rationale for using upside-down English texts was to keep the low-level features such as regular spacing and similarity of letters but reduce possible influences of higher-level processing such as meaning. Figure 4a illustrates C1, in which half of the original texts were rotated and the other half was replaced with Chinese texts. In C2, as demonstrated in Figure 4b, the upside-down texts in C1 were replaced with Chinese texts, and the Chinese texts in C1 were replaced with the original, but upside-down, English texts.

Figure 4. Example of Chinese and upside-down English texts used in Experiment 2. (a) Condition C1 (b) Condition C2.

**Procedure.** The procedure was identical to Experiments 1 except that half of the subjects viewed condition 1 (C1) stimuli and the others viewed condition 2 (C2) stimuli in a between-subject counter-balanced design.

**Analysis.** The analyses were identical to Experiment 1.

Figure 5. An example of (a) stimulus image, (b) text-detector map, (c), attentional map of an English-speaking viewer (5-second viewing), and (d) attentional map of a Chinese-speaking viewer (5-second viewing).

## Results and Discussion

**Models with and without Text-Detector Maps.** The average R and ROC of all 14 English-speaking and 16 Chinese-speaking viewers are shown in Table 3. For English-speaking viewers, one-way ANOVAs showed that the Sali, Cen, TextDet, SC, and SCT maps performed differently in all, text-present, and text-absent images for R, all  $F_s(4; 65) > 8.47$ ,  $ps < .01$ , and for ROC, all  $F_s(4; 65) > 53.78$ ,  $ps < .001$ . SCT predicted attentional maps better than SC in all, text-present, and text-absent images for R, all  $ts(13) > 3.49$ ,  $ps < .01$ , and ROC, all  $ts(13) > 6.61$ ,  $ps < .001$ . For Chinese-speaking viewers, similar results were obtained - the performances of Sali, Cen, TextDet, SC, and SCT maps significantly differed for both R, all  $F_s(4; 75) > 33.91$ ,  $ps < .001$ , and ROC, all  $F_s(4; 75) > 22.86$ ,  $ps < .001$ . SCT yielded better prediction of attentional maps than SC for both R, all  $ts(15) > 4.85$ ,  $ps < .001$ , and ROC, all  $ts(15) > 5.29$ ,  $ps < .001$ . The results of SCT are consistent with Experiment 1 in that the text detector improved the prediction of viewers' visual attention, even in text-absent images.

**Text-Present vs. Text-Absent Images.** For English-speaking viewers, TextDet performed better in text-present images than in text-absent ones for both R,  $t(13) = 6.41$ ,  $p < .001$ , and ROC,  $t(13) = 5.58$ ,  $p < .001$ . For Chinese-speaking viewers, similar results were found: text-present images obtained higher R and ROC than text-absent ones,  $t(15) = 4.97$ ,  $p < .001$ , and  $t(15) = 7.35$ ,  $p < .001$ , respectively.

**English vs. Chinese-Speaking Viewers.** As shown in Figure 6, TextDet predicted English-speaking viewers' attention better than Chinese-speaking viewers' attention for all viewing durations in both text-present images,  $t(7) = 23.12$ ,  $p < .001$ , and text-absent images,  $t(7) = 5.38$ ,  $p < .01$ . These results indicate that the text detector that was designed for English texts performed better at predicting the allocation of attention for English-speaking viewers than for Chinese-speaking ones.

Table 3: The average R and ROC of saliency (Sali), center-bias (Cen), text-detector (TextDet), saliency combined with center-bias (SC), and all combined (SCT) maps as predictors of attentional maps for 5-second viewing. En represents English-speaking viewers, and Ch means Chinese-speaking viewers.

	Sali	Cen	TextDet	SC	SCT
R (En)	0.17	0.17	0.14	0.20	0.21
Text-Present	0.15	0.16	0.16	0.19	0.21
Text-Absent	0.18	0.17	0.12	0.21	0.22
R (Ch)	0.17	0.16	0.12	0.19	0.20
Text-Present	0.15	0.15	0.14	0.18	0.19
Text-Absent	0.18	0.17	0.11	0.20	0.21

## General Discussion

In Experiment 1, we found that adding a text detector to an attention model improved its prediction of viewers' visual attention, even in text-absent images. Our results suggest that non-text objects whose features resemble those of texts (such as high spatial frequency edges) catch a disproportionate share of attention. Based on the current

data, it seems that the viewers' "biological text detectors" are somewhat similar to the artificial system and influence the viewers' distribution of attention when viewing real-world images. From a time-course analysis, it appears that the biological text detector influences the allocation of attention particularly strongly during later stages of image inspection when viewers are increasingly likely to attend to detailed local structures (see Unema et al., 2005) for semantic interpretation of perceived text.

Whereas the results of Experiment 1 could have been caused by the text detection algorithm being sensitive to visual features that generally attract attention, such as edge density, this interpretation becomes implausible given the results of Experiment 2. We found that the text detector designed for English texts predicted English-speaking viewers' attention better than Chinese-speaking viewers', supporting the hypothesis that viewers have developed a "text detector" that is sensitive to text patterns they are familiar with. It is interesting to see that the way we learn to read influences our allocation of visual attention in everyday life, even when there are no texts presented and we are not specifically looking for any texts.

While the present study has demonstrated the influence of language on visual attention in real-world scenes, further research needs to identify the visual features that underlie this effect. This could be achieved by using text detection algorithms for different writing systems and test their individual components as predictors of native and non-native speakers' attention in natural scenes. Besides a more comprehensive understanding of attentional control in humans, such studies may also result in technological advances. Human viewers can easily locate texts in natural scenes, performing clearly better than current text-detection techniques even when the texts are degraded by noise, rotated, distorted, or shown from unusual perspectives. Consequently, the results of this line of research, such as analyzing what features or local structures are actually learned by the biological text detector, might contribute to the development of more effective automatic text detectors, which could, for example, make a great difference to visually challenged people's lives.

# Implicit theories of the causes of weight gain in adults

Nicole Ware

## Abstract

This study sought to explore the range of beliefs about weight gain and whether these beliefs varied according to personal weight management history. A questionnaire specifically designed for the study was completed by 376 participants (94 males, 282 females; mean age 43.65 years,  $SD=13.24$ ). Principal component analysis identified five causal attribution factors which were interpreted as Lack-of-Self-Control, Lifestyle-Limitations, Psychological, Biological/Medical, and Modern-Living. The level of endorsement for these causal attribution factors suggested an acknowledgement of the multiple causes to weight gain. However, the most highly endorsed factor, Lack-of-Self Control, reflected the “commonsense” view of weight gain being a matter of overeating, under-exercising and lacking in self control. Personal weight management history was found to be associated with variations in beliefs with the more effort one had applied to weight management; the more highly they endorsed causes both within and outside of individual control.

**Keywords:** implicit theories, causal explanations, weight gain, obesity.

## Introduction

Obesity is considered a worldwide epidemic (World Health Organization [WHO], 2000) with over half the adult population in many countries classified as either overweight or obese (Bovbjerg, 2008; Lim, Norman, Clifton, & Noakes, 2008; Thorburn, 2005). Overweight and obesity are widely recognized as being associated with enormous psychological, health, and economic costs, both on individual and national scales (Stroebe, 2008). More recently it has been recognized that such costs occur with any level of weight gain. Increases in body weight of less than five kilograms have been found to be associated with increased disease load, with the associations occurring even within the healthy BMI range (Lim, et al., 2008; WHO, 2000). This has contributed to the WHO’s (2000) decision to advocate the prevention of weight gain in adults as the key strategy in managing obesity. This strategy aims to prevent initial weight gain in normal weight adults, as well as preventing further weight gain in those who are already overweight or obese. At an individual level, prevention of weight gain is quantified as gain of less than five kilograms across adulthood (B. A. Swinburn, et al., 2004).

Prevention of weight gain has now become a focus of public discussion and debate, with numerous theories of causes and solutions in the public arena (Faith, Fontaine, Baskin, & Allison, 2007). Individual changes are often asserted as solutions (Lombard, et al., 2009) along with a range of population scale strategies which include education

campaigns to raise community awareness about the importance of healthy eating, healthy weight and physical activity; changes to urban design and land use to encourage physical activity; and reshaping the food supply to increase access to healthy food, restrict access to unhealthy foods and a regulation of the sugar, fat, and salt contents of foods (NOTF Obesity Working Group, 2009).

Understanding the beliefs and attitudes regarding weight gain held within the community is extremely important for the acceptance and successful implementation of population-level interventions aimed at reducing weight gain (Lombard et al., 2009). Personal beliefs and attitudes about a psychological problem constitute an implicit theory (or explanatory model). An implicit theory contains the individual’s understanding of the causes of the problem, the expected course and prognosis. Implicit theories arise from the individual’s personal experiences, but are primarily mediated by the individual’s social and cultural environment (Furnham, 1988). Many reasons for exploring implicit theories have been identified, particularly within a public health framework. The theories held by lay people may contain elements that have been previously overlooked by the scientific community. In addition, the experience of lay people may place them in a position to identify flaws and shortcomings in current scientific theories or models (Entwistle, Renfrew, Yearley, Forrester, & Lamont, 1998; Popay & Williams, 1996). Addressing such differences between lay knowledge and scientific research also helps to increase the community’s perception of the relevance of research and its resulting policy, and hence the acceptance of interventions (Popay & Williams, 1996).

Various studies have examined the beliefs about obesity amongst lay and professional groups such as doctors, nurses, dieticians, and teachers. These studies have generally found that most people did recognize multiple factors as contributing to obesity, but were more likely to recognize factors within the individual’s control. For example, Ogden and Flanagan (2008) in their comparison of general practitioners and lay people found that behavioral causes of obesity (e.g., not enough exercise, eating too much, and too many unhealthy foods) were most strongly endorsed in both groups. Social causes of obesity such as a lack of education, and biological causes, were not strongly endorsed by either group.

Okonkwo and While (2010), in a study involving University students, found reduced physical activity and the promotion and low cost of fast foods to be strongly endorsed, with genetics receiving the lowest endorsement.

However, they found that participants who were overweight and obese were more likely to endorse genetics and the high costs of fruit and vegetables as causes of obesity. This suggests those who have experienced weight gain are more likely to have greater awareness of factors outside of individual control.

Physical inactivity, eating too much of the wrong foods, and mood changes leading to overeating were again found as the most strongly endorsed causes of obesity in a study of beliefs held by British dieticians (Harvey, Summerbell, Kirk, & Hills, 2002), with biological factors again being least endorsed. This study also sought to determine differences in beliefs about obesity compared to overweight. It was found that the dieticians held similar causal beliefs for both overweight and obesity, but that obese people were seen as more responsible for their weight than were overweight people.

These studies provide insight into beliefs about obesity amongst both lay and professional populations. However, obesity is a recognizable medical condition that refers to an excess of body fat (C. L. Ogden, Carroll & Legal, 2003). Obesity has also often been conceptualized as a biological deviation from the 'normal' healthy state (Jutel, 2006). In contrast, weight gain is less visibly recognizable, is susceptible to fluctuations over the lifespan and affects a larger proportion of the population. Furthermore, individuals may fail to recognize their own weight gain over time and fail to recognize their weight problems (Ziebland, Thorogood, Fuller & Muir, 1996). Consequently, implicit theories about weight gain may be different to those of obesity.

One of the few studies to examine the issue of weight gain was conducted by Jackson, Ball & Crawford (2001) who examined the beliefs about the causes of personal weight gain and loss. The causes were assessed through open answer responses. However, categories for response coding were limited so that a full assessment of causal theories was not possible. Despite this, they found that over one third of participants had gained weight over the previous 12 months, and fewer than half of these acknowledged changes in the amount of food or activity alone as a cause of their weight gain. Other causes given were changes in food type, medical conditions, growth, ageing, and "no special reason".

Paxton and Sculthorpe (1999) examined the issues of weight and weight gain by using the Dieting Beliefs and health locus of control scales and found that beliefs about weight varied according to socioeconomic status and weight. They found that the low SES group was more likely to recognize the influence of factors outside the individual's control (e.g., luck, genes) and environmental factors on weight compared to those in high SES. The authors partly attributed this finding to the limited access to resources faced by the low SES group (Paxton & Sculthorpe, 1999). Consistent with Okonkwo and While's (2010) study, overweight participants were more likely to endorse factors outside of the individual's control as well as environmental factors compared to normal weight participants. However,

they were also more likely to hold the belief that weight is internally controlled. The authors suggest that this higher endorsement of both internally controlled and externally controlled factors may result from both an increased sensitivity to the individual focus of weight loss campaigns, as well as an unsuccessful dieting history, although long term history was not examined.

The current study sought to conduct a more comprehensive examination of the range of beliefs/attitudes about weight gain in adults by using questionnaire items generated from both the general public and the literature on obesity and weight gain. Previous research have used limited number of items and/or predetermined summed categories/scales imposed by the researchers, thereby limiting the ability of these studies to fully explore causal beliefs held by the general community. The current study also examined whether implicit theories of weight gain differed on the basis of personal weight management history. Studies on weight loss intervention have reported that overweight individuals viewed their weight problem as arising from their own motivation and physical shortcomings or as a response to specific issues or challenges in their lives (Greener et al., 2010).

## Method

### Participants

The participants (N= 376; 94 males, 282 females; mean age = 43.25, S.D. = 13.64) in the main study were recruited from regional (e.g., Cobar, Dubbo, Parkes,) and metropolitan areas of Australia (e.g., Adelaide, Melbourne, Sydney) through a snowball sampling approach and random distribution of the questionnaire in shopping areas in a major regional centre in central western New South Wales (e.g., Bathurst, Orange).

### Materials

The items to be included in the questionnaire were developed from both a pilot study and a literature review. Twenty participants (11 females, 9 males), took part in the pilot study. The age range was 18-74 years, (mean=38.00, SD=14.51), with participants from both regional and metropolitan areas. Each participant was interviewed individually and asked to provide possible causes of weight gain in adults. Any causal belief identified by two or more participants were phrased into a questionnaire item and included in the final questionnaire. The resultant items were supplemented by items drawn from the literature including government publications and policy documents (e.g., NOTF, 2006; NOTF Obesity Working Group, 2009; National Preventative Health Taskforce, 2010; Smith, et al., 2005; WHO, 2000; WHO, 2002); previous studies that have explored beliefs about weight management, weight gain, and obesity (e.g., J. Ogden & Flanagan, 2008; Okonkwo & While, 2010); and current literature that examine scientific theories of weight gain and obesity (e.g., Eby & Colditz, 2008; Faith, et al., 2007; Greener, et al., 2010; Lombard, et

al., 2009; Stroebe, 2008; B. Swinburn & Egger, 2004; B. A. Swinburn, et al., 2004).

The final questionnaire listed 42 causal items of weight gain. Participants were asked to rate the importance of each causal item on a six point scale (not at all important to extremely important). Demographic information regarding gender, age, location, education level, current weight and height were also obtained. Weight gain was defined in the questionnaire as a gain of more than 5kg above the participant's usual body weight. Participants were also asked about unplanned weight gain, years spent on weight management, degree of effort in weight management.

## Procedure

Participants recruited using the snow-ball sampling approach were given the choice of paper-based or electronic questionnaires. Envelopes were provided with the option of returning directly to the researcher, or through prepaid post. Participants recruited in shopping areas were given the option of completing the questionnaire at that time or at a later time. Those completing the questionnaire at the shopping area were provided with a sealable envelope to ensure anonymity and confidentiality. Reply-paid envelopes were supplied to shoppers who chose to complete their questionnaire at a later time. Questionnaires were distributed over a three week period across a variety of days and times in an effort to include shoppers from a variety of backgrounds. The questionnaire took approximately 15-20 minutes to complete. Return of the completed questionnaire was taken as indication of consent. The overall return rate of paper-based questionnaires was approximately 47%.

## Results

### Preliminary analyses.

Participant's postcode and suburb were used to classify participants as located in a major city, inner-regional, or outer-regional/very remote according to the Australian Standard Geographical Areas - Remoteness Structure developed by the Australian Bureau of Statistics (ABS). Socioeconomic status was calculated according to postcode percentile rankings within Australia using the ABS Socioeconomic Indexes for Areas (SEIFA) data cube 2006. Current BMIs were calculated using reported height and weight. The planned tests were quite robust to violations of distribution, however where skewness was severe appropriate transformations were conducted and transformed data used for analyses. No significant differences were obtained between the participants using electronic and paper versions of the questionnaire with regards to mean factor ratings.

### Main Analyses.

A principal component analysis was conducted on the ratings of the 42 causal items. A Velicer's minimum average partial test (MAP) (Zwick & Velicer, 1986) was used to determine the number of components to be

extracted. Varimax rotation was applied to determine orthogonal factors and enhance interpretability. Only those items with factor loadings greater than 0.30 were included. To further enhance the uniqueness of the factors, items with similar loadings ( $\pm .20$ ) on multiple factors were excluded from the factors and any further interpretation. Mean factor scores were calculated using a sum of scores by factor divided by the number of items (DiStefano, Zhu, & Míndrilă, 2009).

A five-factor solution was extracted from the data which accounted for 50.57% of the variance. Fifteen items were excluded from further analysis due to similar loadings on two or more factors (see Table 1). The first factor, labeled *Lack-of-Self-Control* (Cronbach's  $\alpha=.81$ ), accounting for 12.19% of the variance, consisted of 8 items relating to a lack of control of diet and exercise. Labeled *Lifestyle-Limitations*, the second factor accounted for 11.37% of the variance and included 5 items (Cronbach's  $\alpha=.76$ ). These items reflect the impact of the higher cost of healthy eating, the influence of long and irregular work hours. This factor also included a lack of awareness of the effects of current lifestyle on weight gain. Explaining 10.63% of the variance, the third factor consisted of 6 items (Cronbach's  $\alpha=.85$ ). This factor was labeled *Psychological* to reflect the content of the items (i.e., depression, stress and low self-confidence). This component also included the ageing item (i.e., Normal part of growing older). The fourth factor was labeled *Biological/Medical* and its items related to hormonal, metabolic and medication-related causes. Consisting of 4 items (Cronbach's  $\alpha=.80$ ) it explained 8.27% of the variance. The final factor, explaining 8.11% of the variance, was labeled *Modern-Living* (Cronbach's  $\alpha=.72$ ). This consisted of 4 items reflecting the reduction in physical activity through the use of cars, modern appliances, and electronic entertainment as well as the recent surge in the "diet" food industry.

Mean factor scores were calculated and are presented in Table 1 with mean item ratings (and standard deviations), the corresponding overall item ranking, and the rotated component loadings. Higher mean scores reflect a greater degree of endorsement in causing weight gain. *Lack-of-Self-Control* was regarded as the most important causal factor with its eight items being the top eight ranked items based on means. Although still acknowledged as important, lower means were found for the other causal attribution factors. Pair-wise comparisons were conducted with a Bonferroni adjustment for the ten possible comparisons resulting in a critical  $\alpha=.005$ . The comparisons confirmed that *Lack-of-Self-Control* was rated as significantly more important compared to the remaining factors (all  $t_s > 20.69$ ,  $p < .0001$ ). The ratings of the remaining causal attribution factors did not differ from each other (all  $t_s < 1.92$ ,  $p > .05$ ).

Mean ratings for each factor were compared according to demographic and weight history. A Bonferroni correction was applied to reduce family-wise error rate across the five causal attribution factors resulting in a critical  $\alpha=.05/5=.01$ . Independent samples t-tests showed that females rated the

importance of *Lifestyle-Limitations* higher than did males  $t(365)=-3.06$ ,  $p=.002$ ,  $d=0.39$ . Females also rated the factors of *Psychological* and *Biological/Medical* as more important as causes of weight gain than did males  $t(372)=-3.56$ ,  $p<.001$ ,  $d=0.43$ ; and  $t(361)=-3.38$ ,  $p=.001$ ,  $d=0.41$ , respectively.

A one-way ANOVA showed an effect for location for the factor of *Modern-Living*<sup>1</sup>,  $F(2, 367)=9.88$ ,  $p<.001$ ,  $\eta^2=.05$ . A Tukey's post-hoc analysis (adjusted for uneven group sizes—Tukey-Kramer) with a critical  $\alpha=0.1/3=.003$  to adjust for the three possible pair-wise comparisons, showed that those residing in major cities rated *Modern-Living*<sup>1</sup> as significantly less important than did those residing in either inner-regional or outer-regional/remote areas. A significant difference was also found for location for the *Lack-of-Self-Control*<sup>1</sup> component,  $F(2, 367)=5.75$ ,  $p=.003$ ,  $\eta^2=.03$ . Post hoc analysis showed that those residing in inner-regional areas rated this factor as being significantly more important than those in major cities.

Correlations (all two tailed) showed that age was weakly associated with *Modern-Living*  $r(243)=.180$ ,  $p<.001$ ,  $R^2=.03$ ; with increasing age reflecting increased importance placed on *Modern-Living* as a cause of weight gain. A greater degree of effort in weight management was related to greater endorsement of the *Lack-of-Self-Control* factor  $r(304)=.26$ ,  $p<.001$ ,  $R^2=.07$ . Increasing amount of effort was also associated with increasing importance attributed to the *Lifestyle-Limitations* factor;  $r(300)=.21$ ,  $p<.001$ ,  $R^2=.04$ ; and the *Psychological* factor,  $r(304)=.23$ ,  $p<.001$ ,  $R^2=.05$ . Similarly, the longer the amount of time spent actively managing weight the greater importance attributed to the *Psychological* factor,  $r(244)=.20$ ,  $p=.002$ ,  $R^2=.04$ .<sup>1</sup>

## Discussion

The aim of the current study was to explore the implicit theories held about weight gain and how these vary according to demographics and personal weight management history. Five factors were obtained to explain causes of weight gain. These were *Lack-of-Self-Control*, *Lifestyle-Limitations*, *Psychological*, *Biological/Medical*, and *Modern-Living*. Overall, the level of endorsement for these factors indicated that they were recognized to some degree as being important; however, the *Lack-of-Self-Control* factor was regarded as the most important in causing weight gain. This factor reflects the “commonsense” view of weight gain with its individual focus of eating too much, not exercising enough, and being lazy or lacking in self-control. The high importance attributed to this factor is consistent with obesity studies in which the most endorsed causes are those regarded to be under individual control (Harvey, et al., 2002; J. Ogden & Flanagan, 2008; Okonkwo & While, 2010).

The *Modern-Living* and *Lifestyle-Limitations* factors recognized social and environmental changes that have impacted on current lifestyles. The *Modern-Living* factor incorporated recent increases in the use of technology such as modern appliances, electronic entertainment, and cars as well as the recent increase in availability and consumption of “diet” foods. The *Lifestyle-Limitations* factor acknowledged the contributions to weight gain through time difficulties associated with long and/or irregular working hours, high costs of healthy food relative to unhealthy foods and lack of awareness of the effects of current lifestyle. The final two factors of the current study reflected individual level causes, but those generally recognized as being outside of individual control. The *Psychological* factor included the effects of emotional issues such as depression and stress, as well as ageing on weight gain. Hormonal and metabolic issues and medication effects were expressed in the *Biological/Medical* factor.

The current study also examined how the beliefs about weight gain varied according to demographics characteristics. Females compared to males, regarded the factors of *Lifestyle-Limitations*, *Psychological*, and *Biological/Medical* as being more important in causing weight gain. Increasing age was found to be associated with increasing endorsement for the *Modern-Living* factor as a cause. Unlike previous studies on obesity, no differences were found according to SES or education level.

Some differences were found in the level of endorsement for the causal attribution factors on the basis of location. Those participants living in major cities rated *Lack-of-Self-Control* as less important compared to those living in inner-regional areas. Those in major cities also rated *Modern-Living* of lower importance than did those living in regional and remote areas. These differences may reflect differences in lifestyle and/or limited resources/options available to those living in regional areas of Australia. For example, limited public transport services and centralization of services in regional areas may have increased the reliance on cars and other technologies leading to a greater awareness of the impact of modern living amongst this population.

The current study also sought to examine whether beliefs about weight gain would be associated with the personal experiences of weight management, with those who have experienced unplanned weight gain and unsuccessful weight management more likely to recognize the role of factors involved in weight management that are outside the individuals control than are those who have not experienced such weight difficulties. However, endorsement of the causal attribution factors did not differ on the basis of whether or not one had experienced unplanned weight gain or on whether one had actively managed their weight. Current BMI was also not associated with the levels of endorsement for any of the causal attribution factors. Instead, this study found that greater time spent (in years)

<sup>1</sup> These factors suffered skewness. These were transformed using logarithms, inverses and SQRT as appropriate for statistical tests with t and F statistics reported for transformed data.

Table 1. Rotated factor item loadings, means, standard deviation and rankings for the five causal attribution factors of weight gain.

Factor labels and items	Mean	SD	Rank	1	2	3	4	5
<b>(1)Lack-of-Self-Control</b> (Cronbach's $\alpha=.81$ )	4.22	0.66						
Eating the wrong types of foods.	4.49	0.87	2	<b>.68</b>				
Eating more food than you need	4.50	0.86	1	<b>.63</b>				
Not enough physical activity/exercise.	4.42	0.92	3	<b>.61</b>				
Lack-of-Self-Control.	4.09	1.07	6	<b>.59</b>				
Eating too many convenience foods/take away.	4.13	1.10	5	<b>.58</b>				
Enjoying high fat/high sugar "bad" foods.	4.30	1.01	4	<b>.54</b>				
Too much snacking.	3.84	1.05	8	<b>.54</b>				
Being lazy.	3.97	1.19	7	<b>.54</b>				
<b>(2)Lifestyle-Limitations</b> (Cronbach's $\alpha=.76$ )	3.12	0.98						
Lack of awareness of problems with current eating/exercise habits.	3.13	1.29	20		<b>.63</b>			
Working long hours.	3.16	1.41	19		<b>.58</b>			
Low price of high fat/ high sugar foods compared to fruit and vegetables.	3.24	1.35	16		<b>.57</b>			
Shift work/irregular working hours.	2.92	1.44	25		<b>.56</b>			
High costs of healthy foods (e.g., fruits, vegetables, grains, lean meat).	3.16	1.42	18		<b>.51</b>			
<b>(3)Psychological</b> (Cronbach's $\alpha=.85$ )	3.20	1.00						
Poor self-confidence	2.94	1.31	24			<b>.70</b>		
Loneliness/social isolation.	3.31	1.40	14			<b>.60</b>		
Low self-esteem.	3.30	1.32	13			<b>.59</b>		
Depression.	3.39	1.40	12			<b>.58</b>		
Stress.	3.47	1.27	11			<b>.57</b>		
Normal part of growing older (i.e., aging)	2.80	1.25	26			<b>.53</b>		
<b>(4)Biological/Medical</b> (Cronbach's $\alpha=.80$ )	3.12	1.08						
Medical conditions – e.g. thyroid problems.	3.25	1.43	15				<b>.75</b>	
Side effect of medications.	3.05	1.38	22				<b>.73</b>	
Hormonal/pregnancy related changes in metabolism.	3.19	1.39	17				<b>.70</b>	
Slow metabolism.	3.00	1.28	23				<b>.60</b>	
<b>(5)Modern-Living</b> (Cronbach's $\alpha=.72$ )	3.19	0.95						
Increased use of modern appliances rather than manual labor e.g. ride on mowers, remote controls	3.11	1.30	21					<b>.69</b>
Increased use of cars over walking/cycling.	3.49	1.20	10					<b>.69</b>
Increased participation in sedentary leisure activities (e.g. TV, computers & electronic games)	3.67	1.21	9					<b>.64</b>
Eating too much of 'diet' 'low fat' 'fat free' foods.	2.50	1.43	27					<b>.43</b>

Fifteen items excluded from analysis due to similar loadings on two or more factors:

Emotional 'comfort' eating	Too much soft/fizzy drinks	Too much alcohol
Larger portion sizes.	Increased consumption of refined/processed foods	A lack of nutritional knowledge
Poor family eating habits	Confusing other cues with hunger (e.g., boredom, thirst)	Disruptive life-events (e.g., divorce, grief)
Genetic factors	Giving up smoking	Lack of time for meal planning
Lack of physical activity at work	Advertising and marketing of unhealthy foods	Eating too little of 'diet', 'low' fat, 'fat free' foods

managing weight was associated with more importance being attributed to the *Psychological* factor. Greater effort on weight management was also associated with higher endorsement of the *Lack-of-Self-Control*, *Lifestyle-Limitations*, and *Psychological* factors. This suggests that increased effort in weight management is associated with increased recognition of a wider range of causes to weight gain which can be both within and outside of the individual's control. This is consistent with the findings reported by Paxton and Sculthorpe (1999) in overweight/obese women and by Greener et al. (2010) in participants with an unsuccessful dieting history. Both of these studies reported that these individuals attributed their weight problem to personal short-comings but were also aware of environmental pressures outside of the individual's control. The current finding also suggests that the amount of effort expended on weight management may provide a better account of relevant weight history than actual weight gain or loss.

The current findings suggest that, in general, the community as a whole needs greater levels of education about the contribution of factors outside the control of the individual in causing weight gain. Educating the general public of the multiple contributing factors to weight gain would also lead to greater acceptance of population-level strategies that are not specifically targeted towards those who are already overweight or obese. This is particularly relevant given the consistency between the current findings about weight gain and beliefs about obesity reported in previous studies.

It should be cautioned that the current findings do not reflect causality. Other limitations of the current study include unequal group sizes within the location, SES and education categories which may have impacted on the number of significant differences obtained. For example, only 25% of the sample was male despite the researchers' efforts at recruiting more male participants. This study was also based on self-report, possibly tapping into a social-desirability bias. However, the anonymous nature of the questionnaire should have assisted in reducing this bias.

## Abstract

Many languages have a word class whose speech sounds are linked to sensory experiences (sound symbolism). Here we investigated sound symbolism in touch. Specifically, we performed psychophysical experiments to study the relationship between phonemes of Japanese sound symbolic words and emotional evaluations of objects in contact. Participants expressed the sensation obtained from touched materials using Japanese sound symbolic words and evaluated the comfort of tactile sensation. Our results show the existence of unique associations between the phonemes of the words for expressing the sensation and the evaluations of comfort in touch. Next, we compared the results with those for a condition in which the evaluations of comfort on tactile materials were made without expressing the sensations. We found that when certain phonemes are used for expressing the sensation, the evaluations can be biased.

**Keywords:** Sound symbolism; Tactile sensation; Emotional judgment; Onomatopoeia

## Introduction

Against a classical notion in linguistics that speech sounds and meanings of words are independent, the existence of synesthetic associations between sounds and sensory experiences (sound symbolism) has been demonstrated over the decades (e.g., Fox, 1935; Jespersen, 1922; Köhler, 1929, 1947; Newman, 1933; Sapir, 1929; Taylor, 1963; Werner & Wapner, 1952; Wertheimer, 1958, for early studies) and, more or less, in the languages of the world (e.g., Brown, Black, & Horowitz, 1955; Davis, 1961; Emeneau, 1969; Enfield, 2005; Hinton, Nichols, & Ohala, 1994; Klank, Huang, & Johnson, 1971; Kovic, Plunkett, & Westermann, 2010; Nuckolls, 1999; Voeltz & Kilian-Hatz, 2001). The characteristics and universality of such sensory-sound correspondence have been studied to provide a clue for understanding the development of language abilities (Imai, Kita, Nagumo, & Okada, 2008; Kantartzis, Imai, & Kita,

2011; Maurer, Pathman, & Mondloch, 2006; Westbury, 2004) and language evolution (Ohala, 1997; Ramachandran & Hubbard, 2001, 2003).

It is also known that the sensory-sound correspondence can be found not only in words referring to visual shapes, which were demonstrated in the landmark studies (e.g., mal/mil and buba/kiki for round and sharp shapes in Sapir, 1929 and Ramachandran & Hubbard, 2001, respectively), but also in those referring to tactile, smell, and taste sensations. However, the majority of studies in the area of sound symbolism have been limited to visual-sound correspondence. Consequently, we are investigating the sound symbolic associations in touch, specifically the association between the phonemes of Japanese sound symbolic words (onomatopoeia) for expressing tactile sensations and subjective evaluations of comfort/discomfort for touched objects.

We focus on tactile-emotional evaluations, because compared with other languages, Japanese is known to have a large number of onomatopoeic words for tactile sensations, and because associations between the phonemes of Japanese onomatopoeic words and typical categories of tactile *sensations* (not *emotion*) can be observed. For example, onomatopoeic words expressing a sense of smoothness often use the consonant /s/ in the first syllable as in "sara-sara" [(a) in Table 1], while those expressing roughness often use /z/ in the first syllable as in "zara-zara" [(b) in Table 1]. Similarly, characteristic first consonants are observed in each of the tactile categories, such as /p/ for softness as in "puru-puru" [(c) in Table 1] and /k/ for hardness as in "kachi-kachi" [(d) in Table 1]. More importantly, tactile sensations are strongly connected to changes in the states of comfort and discomfort (Gallace, & Spence, 2010), and although it has been reported that touching objects can evoke distinct emotional states according to the textures of touched objects (Ramachandran,

& Brang, 2008), the associations between speech sound for expressing tactile sensations and touch-induced emotional states are unclear.

Table 1: Typical Japanese onomatopoeic words for expressing tactile sensations.

Sounds	Meanings
(a) Sara-sara	Smoothness
(b) Zara-zara	Roughness
(c) Puru-puru	Softness
(d) Kachi-kachi	Hardness

In the current study, we performed two psychophysical experiments. In the first experiment, when participants touched an object, they were asked to express the tactile sensation using Japanese onomatopoeic words [sound symbolic words (SSWs)] and then rate the comfort of the touched object with the semantic differential (SD) method (referred as the SSW+SD condition). This condition was aimed at specifying the systematic association between phonemes of Japanese onomatopoeic words and tactile-emotional evaluations. Our results demonstrate for the first time the existence of unique associations between them.

Next, we compared the results for the SSW+SD condition with those for a condition in which participants made only the tactile-emotional evaluations (SD-only condition). Since recent brain-imaging studies suggests that processing of SSWs could activate corresponding sensory areas (Arata, Imai, Okuda, Okada, & Matsuda, 2010; Hashimoto, Usui, Taira, Nose, Haji, & Kojima, 2006; Osaka, Osaka, Morishita, Kondo, & Fukuyama, 2004), it is expected that speaking them might affect speaker's subjective evaluation of the touched objects. The results demonstrate that when certain phonemes are used for expressing the sensation, the evaluation can be biased.

## Materials and Methods

### Participants

Thirty naïve participants, aged between 19 and 26 years old, took part in the experiments. Fifteen of the 30 (ten males and five females) performed the experiment in the SSW+SD condition; the other fifteen (ten males and five females) performed the experiment in the SD-only condition. They were unaware of the purpose of the experiments, and they had no known abnormalities of their verbal or tactile sensory systems or any particular skills with respect to touch. They visited a laboratory at the University of Electro-Communications for one day to conduct trials. Informed consent was obtained from the participants before the experiment started. Recruitment of the participants and experimental procedures were approved by the University of Electro-Communication Research Ethics Committee and were conducted in accordance with the Declaration of Helsinki.

### Apparatus and Materials

We selected 120 types of tactile materials for the experiments, including fabrics, papers, metals, leathers, rubbers, woods, sand, rocks, and plastics. Preliminarily, we confirmed that onomatopoeic words for expressing the 120 materials would cover the major phonemes of Japanese onomatopoeic words in touch. When feasible, samples were cut to a size of 6 cm x 6 cm and stacked in layers to 2-mm thickness. The rocks and sand were loose in a container. As illustrated in Fig. 1, participants sat in front of a box with an 8 cm x 10 cm hole in it (the materials box) and placed the index finger of the dominant hand into the box through the hole to touch a material; they could not see a material while they were touching it.

Figure 1: Participant touching a material.

### Procedure

A trial in the SSW+SD condition comprised a describing period, in which participants reported an onomatopoeic word to express the tactile feeling while touching one of the 120 materials, and a rating period, in which they evaluated the comfort/discomfort of the touched material on a seven-point scale (Very comfortable +3, Comfortable +2, Slightly comfortable +1, Neither 0, and three levels, -1 to -3, for uncomfortable feeling) while touching it. In the describing and rating periods, they could freely run their fingers and push on the surface of the material, and the time for answering was not limited. A trial in the SD-only condition comprised only the rating period. In the experiments, the experimenter placed one material in the material box, and the participant touch it and respond, and then replaced it with another after the participant's response. Tactile materials were presented in a random order.

### Results for SSW+SD condition

The results for the SSW+SD condition produced 1800 sets of onomatopoeic words and subjective evaluations of comfort level (120 materials x 15 participants). In 87.1% of all trials (1569 cases), the onomatopoeic word had a two-mora repetition form (e.g. "sara-sara"). We therefore analyzed the relationship between the phonemes of onomatopoeic words in two-mora repetitions form and evaluations of comfort/discomfort using the 1569 instances. The average of the ratings obtained across the 1569 cases was 0.08. This value suggests that half of trials yielded a rating in a comfortable level, and the other half a rating in an uncomfortable level (nonbiased for participant's response opportunities).

We took particular note of the vowels and consonants of the first syllable, which show strong sound symbolic associations (Hamano, 1998). The averages of ratings across trials in which the same phonemes were used in the first syllable were statistically compared with the average of the 1569 cases (0.08) (t-test comparing the average with constant value). Of the vowels, as shown in Table 2, only /u/ had a statistically significant relationship to comfort. Vowels /i/ and /e/ were not used often, but they were deeply related to discomfort (/i/ was marginally significant, and /e/ was significant). Among the consonants, /m/, /h/, and /s/ were related to comfort, while /g/, /z/, /j/, /b/, and /n/ were significantly related to discomfort.

Next, we combined the vowels and consonants of the first syllables and did a similar statistical analysis for the values

(e.g., an analysis based on the value of /sa/ rather than the values of /s/ and /a/ separately). Table 3 shows the results of combinations between the vowels and consonants, which are listed in Table 2. The vowel /u/ was significantly related to comfort with many consonants (e.g., /h/ as in "huwa-huwa", /s/ as in "sube-sube", /t/ as in "tsuru-tsuru", and /p/ as in "puru-puru"). Conversely, /e/ was related to discomfort with any consonant (e.g., /p/ as in "pecha-pecha", /n/ as in "neba-neba", and /b/ as in "beta-beta"). Consonants /m/, /h/, and /s/ were related to comfort regardless of the vowel, while /g/, /z/, /j/, /b/, and /n/ were related to discomfort regardless of the vowel. Vowels /o/, /a/ and /i/ and consonants /p/ and /t/ were related to different levels of comfort depending on the consonant or vowel they were combined with, suggesting that as phonemes, they have only a weak relation to comfort level.

Table 2: Numbers (Num.) and average of ratings (Ave.) of the first vowel and consonant. Only phonemes whose numbers were more than 16 (1 % of 1569 cases) are listed. P-values of statistical analysis to the overall average (0.08) are also shown (+:  $p < 0.1$ , \*:  $p < 0.05$ , \*\*:  $p < 0.01$ , \*\*\*:  $p < 0.001$ ). Red and blue shading indicate that the phoneme is significantly different in positive and negative values, respectively.

First vowel				First consonant			
	Num.	Ave.	$p$ value		Num.	Ave.	$p$ value

## Results for SD-only condition

We compared the results for the SSW+SD condition with those for the SD-only condition to examine the influence of expressing the sensations with sound symbolic words on the emotional evaluation (comfort level). First, we calculated averages of ratings for each tactile material (120 materials) in the SSW+SD (using 1569 cases) and SD-only (using 1800 cases) conditions. The analyses using 240 averaged values (120 materials x 2 conditions) were performed in two domains, in which the averaged values in the SD-only condition were positive (comfort materials) or negative (discomfort materials). For comfort materials (62 materials), the means of ratings across 62 materials were 0.70 in SSW+SD and 0.73 in SD-only. They were not significantly different (paired t-test,  $t(61) = 0.39$ ,  $p = 0.70$ ). On the other hand, for discomfort materials (58 materials), the means across 58 materials were -0.48 in SSW+SD and -0.73 in the SD-only. There were significant differences between the values ( $t(57) = 3.41$ ,  $p < .001$ ). These statistical analyses indicate that expressing tactile sensations with sound symbolic words while touching materials does not affect the emotional evaluation if the material is originally comfortable. However, when a touched material elicits discomfort, the emotional evaluation can be attenuated by expressing the sensation with sound symbolic words.

To clarify the systematic association between phonemes of onomatopoeic words and their influence on the evaluation, we made distribution maps of 120 materials as shown in Figs. 2 and 3, respectively. The phonemes represent each material in the maps. The representing phonemes were determined from the first syllables used for expressing the sensations most in the trials in the SSW+SD condition. Ones in the right-side area in the maps are comfortable materials and vice versa. In addition, ones in the upper side in the maps indicate materials whose comfort levels are improved (Left side: attenuated discomfort. Right side: enhanced comfort) and vice versa. Numbers of phonemes in the upper and lower right side areas are almost identical in the maps. On the other hand, more phonemes are located in the upper left area (attenuated discomfort) than in the lower left area (enhanced discomfort). This means that the comfort levels were systematically biased toward comfort for the discomfort materials, which agrees with the previous statistical analyses.

The differences in the effect of attenuation or enhancement according to the phonemes were statistically examined. We collected phonemes whose numbers in the comfort or discomfort area were more than six (5% of 120 materials) and calculated the means of differences of rating values in the SSW+SD condition from those in the SD-only condition across their corresponding materials. Figure 4 shows the trends for the comfort materials. For vowels, /u/ slightly enhances the comfort (marginally significant effect), but /a/ attenuates the comfort. For consonants, none of the phonemes affected comfort levels for the comfort materials. Figure 5 shows the trends for the discomfort materials.

When the phonemes, /u/ in vowels, /z/ and /p/ in consonants, were used for expressing the tactile sensation, the level of discomfort can be attenuated. Some negative values in comfort level (discomfort materials) became positive (perceived as comfort).

Figure 2: Distributions of vowels according to the values in the SD-only condition (horizontal axis) and difference of SSW+SD from SD-only (vertical axis).

Figure 3: Distributions of consonants according to values in the SD-only condition (horizontal axis) and difference of SSW+SD from SD-only (vertical axis).

Figure 5: Difference of ratings in the SSW+SD condition from those in the SD-only condition for the phonemes in the discomfort area. The data for vowels (left) and consonants (right) are shown with the number and statistical differences from zero. \*\*:  $p < 0.01$ , \*\*\*:  $p < 0.001$ .

## Discussion

### Sensory Category and Sound Symbolism

Humans categorize sensory inputs using words, and words are important indexes in investigating such sensory categories. Previous touch studies identified major factors in object recognition through touch and established standards of classification based on physical properties of materials or in terms of sets of adjectives (Hollins, Bensmaïa, Karlof, & Young 2000; Hollins, Faldowski, Rao, & Young, 1993; Picard, Dacremont, Valentin, & Giboreau, 2003; Tiest, & Kappers, 2006). However, the studies did not discuss sensibilities, such as like and dislike or comfort and discomfort, and to our knowledge, there has been no research regarding the association between touch-induced emotional states and sound symbolic words.

In the experiment in the SWS+SD condition, we found a strong association between comfort and the vowel /u/ and consonants /m/, /h/, and /s/ in the first syllables. If similar sensory categories are expressed using onomatopoeic words with similar phonemes, it will be possible to clarify the categories of comfort/discomfort, which is difficult to study directly. Since the tactile sensations described with the phonemes /m/, /h/, and /s/ seem different, as with "moko-moko" and "huka-huka" for squishiness and "sara-sara" for smoothness, these phonemes might be originated from different categories of comfort. Similarly, for discomfort, the vowel /i/ as in "chiku-chiku" for pointiness and /e/ and consonants /n/ and /b/ as in "neba-neba" and "beta-beta" for stickiness, and consonants /j/, /z/, and /g/ as in "jori-jori," "zara-zara," and "gori-gori" for roughness may represent different uncomfortable categories.

### Uniqueness of Tactile Sound Symbolism

Phonemes related to tactile comfort or discomfort, together with the meanings of general sound symbolism in Japanese onomatopoeic words, are summarized in Table 4 (see Hamano, 1998). The association between the vowel /u/ and comfort has not been identified in the general sound symbolism. For vowel /i/, tactile sensations can be seen as analogous to general sound symbolism, but the association with discomfort seems to be particular to tactile sensation. The association of /e/ with discomfort can be seen as

analogous to general sound symbolism. For consonants, no association between comfort and consonants /m/, /h/ and /s/ has been suggested. For discomfort, the tactile perception and comfort level agree with general sound symbolism for /n/. But it is difficult to analogize the comfort level for /b/ from general sound symbolism, and the association of /z/, /j/, and /g/ with discomfort also appears to be specific to the tactile sense.

As for consistency between modalities, there seems to be similar trends in the sound symbolic relationships between phonemes and perceptual experiences regarding touch and tastes. According to Sakamoto and Chiba (2005), vowel /u/ and consonants /s/ and /h/ are associated with positive evaluations of tastes, while vowels /i/ and /e/ and consonants /n/, /z/, /j/, /g/, and /b/ are associated with negative evaluations. In addition, as for the generality of our results, although the sound symbolism is observed in the languages of the world, whether the trends obtained in our experiments are universal or not is an issue awaiting further investigation.

Table 4: Phonemes related to tactile comfort or discomfort, together with the meanings of general sound symbolism in Japanese onomatopoeic words.

	Comfort	General sound symbolism	
/u/	+	Small round holes/ projections	Specific
/i/	-	Lines, straight elongations	Specific
/e/	-	Coarse, vulgar, unsuitable	Analogous
/m/	+	Indistinct, unclear	Specific
/h/	+	Softness	Specific
/s/	+	Smoothness	Specific
/n/	-	Sticky, uncomfortable	Agree
/b/	-	Taut	Specific
/j/	-	Abrasive	Specific
/z/	-	Abrasive	Specific
/g/	-	Touching a hard surface	Specific

### Affection of Sound Symbolic Words on Evaluation

We found that when certain phonemes are used for expressing sensations for the touched material, the evaluations of comfort levels can be biased. Specifically, when /u/ was used, the bias was always toward comfort, which agrees with the association between phonemes and emotional evaluations in Table 2. But neutral phonemes /a/ and /p/ affect the evaluation. In addition, consonant /z/, which is associated with discomfort, attenuated the discomfort. Considering that emotional states can be evoked by the sensations automatically (Ramachandran, & Brang, 2008) and how words are articulated can be a possible mechanism relevant to sound symbolism (Ohala, 1983), the sound symbolism of comfort and discomfort for the tactile sense may be affected by phonetic (acoustic) comfort or discomfort, as observed in our experiment. But explaining the association is a problem for future research.

## Abstract

Much recent empirical research has explored the influence of moral evaluations on judgments about the intentionality of foreseeable side-effects of actions. Research on this ‘Side-Effect effect’ (also called the ‘Knobe effect’) has relied almost exclusively on vignette-based surveys, which have serious limitations when used in isolation. We present a novel behavioral methodology that tests the Side-Effect effect in two previously unexamined contexts: (i) judgments of real (rather than hypothetical) actions, and (ii) judgments about one’s own actions. The results suggest that judgments about one’s own actions tend to show a reverse Side-Effect effect: actors judge that (real) positive side-effects of their own actions are intentional whereas negative ones are not. The use of non-hypothetical situations also appears to attenuate the standard Side-Effect effect, which raises interesting challenges for standard theoretical accounts. These results provide preliminary evidence that the Side-Effect effect is driven by the same mechanisms underlying other asymmetries in causal attribution.

## Introduction

Notions of ‘intentionality’ and ‘causation’ are crucial in the way we understand our own and others’ mental lives, as well as a range of social interactions (e.g. Gergely, Nadasdy, Csibra, & Biro, 1994; Gopnik, *et al.*, 2004; Leslie & Keeble, 1987; Sloman, 2005; Woodward, Sommerville, & Guajardo, 2001). There has recently been a surge in research on folk understandings of these notions, much of it by experimental philosophers (e.g. Adams & Steadman, 2004a, 2004b; Knobe, 2003, 2004, 2006; Machery, 2008; Nadelhoffer, 2006; Nado, 2008; Uttich & Lombrozo, 2010). This research has revealed that folk judgments often display some surprising patterns. Perhaps the canonical example is the so-called ‘Side-Effect effect’ (also called the ‘Knobe effect’): experimental participants judge that a foreseeable side-effect of an action is more intentional when the side-effect is morally bad than when it is morally good. This paper develops a novel experimental method to investigate the Side-Effect effect that avoids some of the limitations of previous methods. Moreover, we report findings that

suggest that the Side-Effect effect is an instance of a much more general pattern of actor-observer biases, rather than a distinct phenomenon in its own right.

## The Side-Effect Effect

Consider a company chairman who acts to maximize profit, even though that action has the (foreseeable) side-effect of harming the environment. Suppose also that the chairman does not care about the environment; the occurrence of this side-effect is irrelevant (in any way) to his decision. Knobe (2003) found that 85% of participants judged that the chairman had nonetheless *intentionally* harmed the environment. When the program had the side-effect of helping the environment, though, only 23% of participants judged that the chairman had intentionally helped the environment (Knobe, 2003). In both vignettes, the chairman’s explicit goals (i.e., his explicit intentions) and actions remain the same, yet people’s judgments about whether he intentionally brought about the side-effect change significantly depending on the valence of the side-effect. This influence of outcome valence was present cross-culturally (Knobe & Burra, 2006), in four-year-old children (Leslie, Knobe, & Cohen, 2006), and for a range of mental state ascriptions besides simply intentionality (Pettit & Knobe, 2009). While there is general agreement that the intentions of the actor should influence our moral evaluations, it is less clear why the converse should hold. Moral concerns seemingly ought not to have a pervasive impact on what appear to be straightforward judgments about an actor’s mental states (though see Bratman, 1987 and Uttich & Lombrozo, 2010, for defenses of this influence).

Two different types of theories have been offered to explain the Side-Effect effect. Side-effect-centered theories hold that the different responses arise because of properties of the side-effect: some feature of negative or positive side-effects leads the actions to be judged as intentional or unintentional (respectively), or both. For instance, perhaps negative side-effects are always thought to be brought about intentionally (Knobe, 2004, 2006; but see also Pettit & Knobe, 2009, for an updated view), or negative cases require the actor to judge trade-offs (Machery, 2008). Alternately, the fact that an action violates the generalized

norm against bringing about negative outcomes might (rationally) be informative about the actor's mental state, since norm-violation typically requires additional reasons or intentional action (Uttich & Lombrozo, 2010).

In contrast, process-centered theories hold that our judgments would be symmetric in the two conditions, except that one of the situation-types (or both) elicits a mental process that alters or biases our judgment away from our typically symmetric intuitions. Various influencing processes have been suggested: a negative emotional reaction to the chairman (Nadelhoffer, 2006); a desire to blame based on conversational pragmatics of intentional language (Adams & Steadman, 2004a, 2004b); an asymmetric responsibility judgment (Wright & Bengson, 2009); or a distinct "moral mechanism" (Nado, 2008).

The Side-Effect effect has been studied almost exclusively using vignette-based surveys, which arguably have serious limitations when used in isolation. Vignettes focus on hypothetical situations in which many important (in the real world) properties and conditions are left unspecified. Exactly what information is included in (or omitted from) a vignette has been shown to have a substantial effect on people's judgments (Gugliermo & Malle, 2010; Mele & Cushman, 2007; Phelan & Sarkissian, 2008). Moreover, vignettes describe hypothetical situations, and previous research has found that judgments can differ substantially when provided in response to real rather than hypothetical situations. For instance, experimental participants reveal different utility functions when they are given real and hypothetical scenarios (List & Gallet, 2001; Murphy, Allen, Stevens, & Weatherhead, 2005; Neill, Cummings, Ganderton, Harrison, & McGuckin, 1994). Vignettes also require (almost always) that the experimental participant be an observer, not the actor. Thus, it is an open question whether the Side-effect effect occurs when an individual judges the intentionality of the side-effects of her own actions.

### Actor-Observer Asymmetries

Actor-observer asymmetries have been found in a wide range of domains. For instance, actors and observers largely attend to different aspects of a social interaction (Malle & Pearce, 2001). Actors are willing to engage in riskier behaviors than observers will condone (Fernandez-Duque & Wifall, 2007) and we appear to hold ourselves to different moral standards than we hold others to (Nadelhoffer & Feltz, 2008). One classic asymmetry is the Actor-Observer hypothesis in causal attribution (Jones & Nisbett, 1971): we tend to emphasize internal dispositional factors (e.g., attitudes, personality traits) as the causes of other people's actions, and aspects of the external situation (e.g., social constraints, situational factors) as the causes of our own actions. Recent research suggests the classic formulation is an oversimplification; instead of a simple internal/external distinction, actors tend to emphasize their reasons for acting (the beliefs, desires, and values that contributed to their decision to act), whereas observers tend to cite the causal

history of these reasons, including the attitudes, personality traits, and upbringing of the actor (Knobe & Malle, 2002).

A recent meta-analysis found little evidence for a general Actor-Observer asymmetry, but did find evidence for one that was mediated by the valence of the action (Malle, 2006). Observers tend to use more internal explanations than actors when explaining a negative action, but *fewer* internal explanations when explaining a positive action:

Table 1: Influences on causal attribution (adapted from Malle, 2006)

	Negative Valence	Positive Valence
<b>Overall</b>	$\text{diff}_A < \text{diff}_O$ <sup>1</sup>	$\text{diff}_A > \text{diff}_O$
<b>Real Situations</b>	$\text{diff}_A < \text{diff}_O$	$\text{diff}_A > \text{diff}_O$
<b>Hypothetical Situations</b>	$\text{diff}_A < \text{diff}_O$	$\text{diff}_A \approx \text{diff}_O$

Malle (2006) found that the valence-modified actor-observer bias was magnified when participants explained real events (middle row of Table 1). For hypothetical events, however, there was no difference between actors' and observers' explanations of positive actions. This suggests that, at least when explaining our own actions, it makes a difference whether the action is real or hypothetical.

This paper presents a novel experimental method in which participants judged real actions from either an actor or an observer role. We used a  $3 \times 3$  design that varies role {Actor, Observer, Motivated Observer} between-participant and side-effect valence {Neutral, Positive, Negative} within-participant. Side-effect-centered theories largely predict that the actor-observer manipulation should make no difference, since actors and observers should share the same conceptual asymmetries. The exception is the "Rational Scientist" view of Uttich & Lombrozo (2010), which arguably predicts that there should be no Side-Effect effect in the actor condition, regardless of outcome, since one presumably already knows one's own mental state. Most process-centered theories do not make a determinate prediction, since they leave unspecified whether and how the process that causes the asymmetry applies to judgments of one's own actions. Finally, if participants exhibit the asymmetric pattern of judgments characteristic of the valence-modified Actor-Observer hypothesis, then it is likely that the Side-Effect effect is due to the same mechanisms driving asymmetries in causal attributions.

## Experiment

### Participants

46 participants from the McGill, Concordia, and Carnegie Mellon University communities were divided into the Actor

<sup>1</sup> 'diff<sub>A</sub>' and 'diff<sub>O</sub>' refer to the difference between the number of internal and external reasons given by actors and observers, respectively, in the different conditions.

(N = 16), Observer (N = 15), and Motivated Observer (N = 15) conditions. Participants were mostly undergraduates; all were fluent in English and without cognitive deficits.

## Method

The experiment involved a computer game in which the participants (in the Actor condition) generated their own actions, discovered the consequences of these actions, and judged whether they had brought about those consequences intentionally. The game involved a computer interface where each movement of a joystick (up, down, left, or right) led to one or more colored balls being displayed on the computer screen. One of these balls (the red one) was the 'goal ball' and each time the actors got this ball they were rewarded with 10 tokens. Participants in the Actor and Motivated Observer conditions were told that they would redeem the tokens for money at the end of the experiment (but were not provided with the 'exchange rate'); participants in the Observer condition were simply told that collecting tokens was the goal of the game.

The experiment had four phases. In the *Practice* phase, participants in every condition (Actor/Observer/Motivated Observer) played the computer game. During this phase, a joystick movement up deterministically produced a red ball (and so 10 tokens), while movements in all other directions produced a different color ball (and so no tokens). Each action thus produced a single consequence. Participants continued until they generated the red ball on six consecutive trials. At this point, the connections were shuffled (without notice) so that each movement produced a different color ball than before, and participants continued until they again generated the red ball six consecutive times by discovering and then moving in the new rewarded direction. The Practice phase continued until the movement-ball connections had been shuffled three times.

**Actor Condition** Participants in the Actor condition then moved (without notice) to the *Neutral* phase. This phase was identical to the practice phase, except that participants now received *two* balls after each joystick move. A move in the "rewarded" direction always produced both a red ball and a white ball, and every other move resulted in a random pair of unrewarded balls (white, yellow, blue, or green). The white ball thus played the role of a foreseeable side-effect: participants quickly learned that it always appeared with the red ball, but were indifferent to its occurrence. The white ball was introduced after the Practice phase to ensure that participants were motivationally neutral towards it.

The rewarded direction was randomly selected at the start of the Neutral phase. Once participants had made six consecutive moves in that direction, the rewarded direction would change and participants would have to rediscover it. The Neutral phase ended when the participant discovered the rewarded direction after the third change of ball-movement connections.

Participants then entered either the *Negative* or *Positive* phase (order counterbalanced between participants). In these

phases, participants were informed that generating the white ball now had consequences: a randomly chosen other participant in the experiment (i.e., *not* the participant) would either gain (Positive) or lose (Negative) three tokens for each white ball that the participant generated (no others were actually helped or harmed, however). As in the Neutral phase, participants continued until there had been four different rewarded positions. After completing one of these phases, Actor participants were informed of the change in the valence of the white ball, and then performed the other phase.

Throughout all three non-practice phases (Neutral, Positive, and Negative), the following two questions were asked at regular intervals:

Action question: You moved [direction]. How intentional was this?

Color question: You got a [color] ball. How intentional was this?

The Action question was always presented directly after a joystick move, and the Color question was presented after the ball display screen. We are particularly interested in responses about the white (side-effect) ball after participants had already discovered the currently rewarded direction. In this case, the participants presumably could foresee that they would get the white ball, so the white ball is a foreseen side-effect of their action. Answers were reported by clicking on a (540-point) rating scale with left-middle-right anchor points of "not at all intentional", "somewhat intentional", and "completely intentional".

**Observer Condition** In the Observer condition, participants performed the practice phase, but then watched a video of an actor playing the Neutral phase instead of playing it themselves. Participants were told that the other individual was receiving real money when she got red balls. The actor's hand, joystick, and computer screen were shown, but not her face. Whenever the actor was asked an Action question, participants observed her answer "completely intentional." But instead of observing the actor answer for the Color question, the video paused and participants were asked:

Color question (Observer): Julie got a [color] ball. How intentional was this?

Participants were able to replay the video as much as desired before providing an answer. After the Neutral phase, participants observed the same actor in the Positive and Negative phases. Participants were told the relevant valence information, and the video order of the Positive and Negative phases was counterbalanced between participants. As a comprehension check, participants were also given a follow-up questionnaire asking whether the actor was trying to get the white ball in the Positive and Negative phases.

**Motivated Observer Condition** The Motivated Observer condition was identical to the Observer condition, except that participants were informed that they were the individual who had been randomly selected as the 'other participant' to

gain (Positive) or lose (Negative) three tokens whenever the actor got the white ball. They were reminded that tokens were redeemable for actual money.

## Results

There were no order effects, so different orderings were pooled for further analyses. Although the questions used a 540-point rating scale, responses largely concentrated around the three labeled points, indicating that many participants interpreted the scale as categorical. We thus transformed the data into a five-point scale, where each category corresponded to an equal-length segment of the original line. This transformation captured the generally categorical use of the line while preserving information about those few participants who used between-label points in their answers. Intentionality ratings for the goal (i.e., the red ball) were all at ceiling. In contrast, mean intentionality ratings for the foreseen side-effect (i.e., the white ball) are shown in Figure 1 (error bars indicate confidence intervals).

In the Actor condition, a planned, one-way within-participants ANOVA revealed a significant effect of phase valence ( $F(2, 42)=6.09, p<.05$ ). Post hoc Tukey HSD comparisons revealed that the Positive phase ( $M=3.18, SD=1.34$ ) led to significantly higher ratings than the Neutral ( $M=2.10, SD=1.36$ ) and Negative ( $M=2.09, SD=1.25$ ) phases,  $p<.05$ ; the latter two were not significantly different. Participants in the Actor condition thus rated the foreseen side-effect as significantly more intentional when it had a positive valence than a negative one, as found in standard actor-observer biases in causal attribution. A planned, one-way within-participants ANOVA did not reveal a significant effect of valence in the Observer ( $F(2, 42)=0.36, p=.69$ ) or Motivated Observer ( $F(2, 42)=0.48, p=.62$ ) conditions. The conditions were designed to also permit a statistical comparison of ratings from different conditions. One-way between-participants ANOVAs revealed significant effects of participant role for the Neutral ( $F(2, 42)=9.33, p<.05$ ) and Negative ( $F(2, 42)=6.97, p<.05$ ) phases, but not for the Positive phase ( $F(2, 42)=1.3, p=.28$ ). Actors had significantly different ratings than both the Observers and the Motivated Observers, except when the side-effect was positive.

Since every participant experienced all three valence phases, we can also analyze the rating patterns of each individual. We define ‘POS’ participants to be those who gave significantly higher intentionality ratings for the Positive phase compared to the Negative phase. As predicted by the valence-modified actor-observer hypothesis, the frequency of POS participants was significantly greater in the Actor condition (8/16 participants) than in the Observer condition (4/15 participants),  $\chi^2(1, N=30)=.96, p<.05$ , or Motivated Observer (2/15 participants) conditions,  $\chi^2(1, N=30)=1.0, p<.05$ . We can also approximate forced-choice probes (common in Side-Effect effect experiments) by further discretizing intentionality ratings into a binary variable (“Side effect was intended” iff rating  $\geq 3$ ). For the Actor

condition, the positive side-effect was significantly ( $p<.05$ ) more likely to have been rated as intentional than the negative one (75% vs. 38%). There was no corresponding difference in the Observer (86% vs. 73%;  $p>.05$ ) or Motivated Observer (73% vs. 86%;  $p>.05$ ) conditions.

## Discussion

When asked to judge their *own* actions, participants were systematically more likely to judge those actions as intentional when the foreseen side-effect was positive rather than negative; that is, they exhibit something like a reverse Side-Effect effect. This pattern of results closely mirrors the valence-modified actor-observer hypothesis in causal attribution, where actors are more likely to cite internal dispositional factors as the causes of their positive actions than their negative ones. This suggests that the mechanisms driving the Side-Effect effect are plausibly the same ones driving asymmetries in causal attribution, although the nature of these mechanisms is still an open question.

Process-centered accounts focus primarily on the motivations of the observers. While these accounts have not made explicit predictions about the actor case, it is clear that in moral scenarios actors and observers often have different motivational pressures. Actors may have an incentive to minimize their responsibility (blameworthiness) for negative side-effects while overestimating their responsibility (praiseworthiness) for positive ones. Observers do not have these same concerns, and may even have incentives that tend in the opposite direction. However, we found that actors and observers differed in their intentionality judgments even for neutral side-effects, a result that cannot be explained by process-centered accounts. This difference is instead plausibly explained in terms of the epistemic differences between actors and observers. Actors have greater access to their own intentions, and thus are more aware that the side-effect (regardless of valence) was not among their goals. The observers do not have direct access to the mental states of the actor and thus they may rely more heavily on the behavior of the actor and the norms of the situation as a guide to her intentions.

This epistemic explanation fits nicely with the ‘Rational Scientist’ view, wherein epistemic differences between

norm-conforming and norm-violating cases drive the asymmetries in observer judgments. However, these epistemic considerations alone are unable to explain the reverse side-effect for actors, because actors have (at least perceived) direct access to their own mental states. It seems likely, then, that a combination of epistemic and motivational factors is necessary to explain the full range of results. Further research should explore this possibility.

Interestingly, we did not find a significant difference between judgments in the Positive and Negative phases in the Observer condition, as has typically been found using vignette studies. There are several possible reasons for this null result. One explanation is that we used visually presented situations involving real people rather than hypothetical vignettes. The abstract nature of vignettes potentially magnifies various distorting effects; for example, participants are perhaps less likely to believe the hypothetical chairman's reported intentions and more likely to be swayed by a moral evaluation of his actions. Another (not mutually exclusive) possibility is that the side-effect in the present experiment was not sufficiently negative or positive from the perspective of the observers. This explanation seems unlikely, however, since no significant difference was found even in the Motivated Observer condition where the side-effect directly affected the participant. Similarly, Feltz, Harris, & Perez (2010) found no significant Side-Effect effect for observer conditions using realistic settings, suggesting that our finding is not simply an artifact of our experimental design. Finally, an explanation could be given from the perspective of the 'Rational Scientist' view: the norms of computer games in psychological experiments differ from the norms of corporations affecting the environment, and it might be that the observers did not believe the actors in the experiment were violating any norms. This explanation is in some tension, however, with the fact that individuals were observed to violate the generalized norm not to harm others.

The results we report do not provide a definitive connection between the Side-Effect effect in vignette studies and judgments in realistic settings. The vignette results may plausibly generalize in cases where the side-effect valence is strongly negative or positive, when bringing about the negative side-effect involves violating a norm, or when there is greater psychological distance between the participant and the person whose actions are being judged (e.g., when reading a news article or listening to a description), although we currently have no evidence that this is the case. It is clear, however, that the Side-Effect effect should be situated within a more general class of valence-mediated actor-observer biases, and that the connections between these biases and folk psychological judgments warrant further investigation.

## Abstract

Research on human causal learning has largely focused on strength learning, or on computational-level theories; there are few formal algorithmic models of how people learn causal structure from covariations. We introduce a model that learns causal structure in a local manner via prediction-error learning. This local learning is then integrated dynamically into a unified representation of causal structure. The model uses computationally plausible approximations of (locally) rational learning, and so represents a hybrid between the associationist and rational paradigms in causal learning research. We conclude by showing that the model provides a good fit to data from a previous experiment.

**Keywords:** Causal learning; causal Bayes nets; prediction-error learning; algorithmic level

## Introduction

From a young age, we spontaneously, and often effortlessly, come to understand the causal structure of the world, and then use that knowledge to both predict what might happen in the future and also design actions that will achieve our goals (e.g., Gopnik, *et al.*, 2004; Sloman, 2005). Our focus here is causal learning from covariational data: how do people learn the causal structure of the world from a sequence of observations or interventions of that world?

Causal learning can usefully be separated into the related-but-distinct problems of representation and dynamics—*what* is learned and *how* is it learned. In this paper, we develop a novel account of causal learning that, at a high level, uses quasi-associationist processes to learn directed graph-like causal representations. It is thus a hybrid of the standard rationalist vs. associationist approaches to causal learning.

## Representations of Causal Structure

The development of causal Bayesian networks prompted a major advance in our understanding of causal knowledge. A causal Bayes net has two components: (i) a directed acyclic graph (DAG) whose nodes represent variables and directed edges represent direct causal relations (see Figure 1); and (ii) a probability distribution that encodes how causes influence their effects. These two elements represent qualitative and quantitative causal structure, respectively,

and are connected by a pair of assumptions (Markov and Faithfulness) that capture the ways in which causal structure manifests in observed data. Sloman (2005) and Spirtes, Glymour, & Scheines (1993) provide useful expositions of the causal Bayes net framework.

Figure 1: Prototypical 3-variable causal Bayes nets

There is substantial evidence that the type of structural knowledge captured by a causal Bayes net—or at least, the directed graphical model part—is necessary to account for many causal reasoning abilities. One hallmark of *causal* reasoning, rather than correlational, is that cases involving observations vs. interventions are treated differently (Sloman & Lagnado, 2005; Waldmann & Hagmayer, 2005). For example, one can infer, from an observation of a professor's gray hair, that she likely has many publications. No such inference follows if she instead intervened to dye her hair gray. Causal Bayes nets can straightforwardly account for this difference, as interventions are represented by 'graph surgery,' where a variable that is intervened upon is separated from its typical causes (Spirtes, *et al.*, 1993). This surgery changes the informational relations, and so one's inferences can be different in the two situations.

Some aspects of causal knowledge are not easily represented by this formalism (e.g. the spatiotemporal relations between causes and effects), but it seems to provide a good account of people's representations of causal structure. Thus, we aim to develop a theory of causal learning in which people learn a directed graph (perhaps acyclic, though we will allow for cyclic structures).

## Dynamics of Causal Structure Learning

Theories about how people use covariation to learn directed graph representations can be divided roughly into *rational* and *heuristic* accounts of causal learning. Rational accounts

model causal learning as rational inference. These include constraint-based algorithms (e.g., Glymour, 2003; Gopnik, *et al.*, 2004), and those based on Bayesian inference (e.g., Steyvers, *et al.*, 2003; Griffiths & Tenenbaum, 2005). They are usually intended at the computational level of analysis, as they show how the cognitive system's performance solves the problem faced by that system, but do not attempt to characterize the underlying cognitive processes. There have been some recent attempts to develop algorithmic (i.e. process) models of causal learning based on approximations of Bayesian inference (e.g., Bonawitz, *et al.*, 2011). These models have so far only addressed causal strength learning, and it is not clear how to extend them (in a computationally tractable manner) to structure learning.

Heuristic accounts of causal learning propose that people use various cues to suggest and modify causal hypotheses in a not-necessarily-rational (though presumably sensible) manner. Causal model theory (Waldmann, 1996) proposes that learners use cues such as covariation, temporal order, and spatial proximity to select an initial causal structure and adjust it in the face of inconsistent data (Lagnado, Waldmann, Hagmayer, & Sloman, 2007). Causal model theory has never been entirely formally specified, though some parts have received formal treatment.

The local computations model (Fernbach & Sloman, 2009) attempts to explain how learners use data from interventions to learn a causal structure. The key idea is that, when a variable is intervened upon and other variables change, the learner infers that the intervened-upon variable caused those other variables. Critically, all learning in this model is local, as people evaluate individual causal relations rather than entire graphs. The model we present here adopts this important insight and extends it to all covariation-based structure learning, including learning from observations.

The single-effect learning model (Waldmann, *et al.*, 2008) also assumes that people focus on evaluating single causal relations. It is a model of learning from observations, and proposes that learners estimate the causal power (Cheng, 1997) of each potential cause of an effect. If a variable has sufficient (estimated) causal power, then the learner accepts the causal relation and integrates it with her previous causal knowledge. This model has found some empirical support in both humans and rats (Waldmann, *et al.*, 2008).

Our model adopts the single-effect learning model's focus on causal power, and the integration of these individually learned relations into a unified causal structure. However, the standard causal power theory is a computational theory that makes no commitment to underlying processes. Danks, Griffiths, & Tenenbaum (2003) provided a prediction-error-based model of causal strength learning whose equilibrium states are causal powers, and so their model can be viewed as an algorithmic implementation of the causal power theory. Moreover, its basis in prediction-errors is consistent with neuroscientific evidence that the right lateral prefrontal cortex encodes prediction-error signals during causal learning (Corlett, *et al.*, 2004; Turner, *et al.*, 2004).

Another lacuna in the single-effect learning model is that it does not explain how the learner uses a causal power estimate to determine whether a link actually exists. We thus provide a decision procedure for causal relation acceptance based on both the learner's point estimate and her confidence in that estimate. This addition allows us to model the dynamics of learning for directed graphs that are more complex than the single-effect structure.

## The LPL Model

The Local Prediction-error Learning (LPL) model aims to explain how observations and interventions are used to learn causal structure when one has relatively little prior knowledge. We do not model many other relevant sources of information, including verbal communication, reasoning, or spatiotemporal information. The model does assume that the learner knows the functional form of the causal relations and (when relevant) the expected temporal delay between causes and effects.

The LPL model begins with an initial causal structure hypothesis: a directed graph representing the individual's prior beliefs, where an edge indicates an *a priori* belief that there is a causal connection, and absence indicates only agnosticism.<sup>1</sup> For typical experiments in which participants have little prior knowledge, this will be an empty graph. The model alters this causal structure hypothesis by adding or removing single edges, thereby reducing the structure learning problem to the simpler task of evaluating individual causal relations. Multiple experimental results suggest that learners focus primarily on single causal relations (e.g., Gopnik *et al.*, 2004; Waldmann, *et al.*, 2008), presumably because of the computational complexity of evaluating larger structures.

Figure 2 shows a high-level overview of the LPL algorithm. The key pieces to be explained are the Causal Strength Estimates, and how the Decision Procedure changes the Causal Structure Hypothesis.

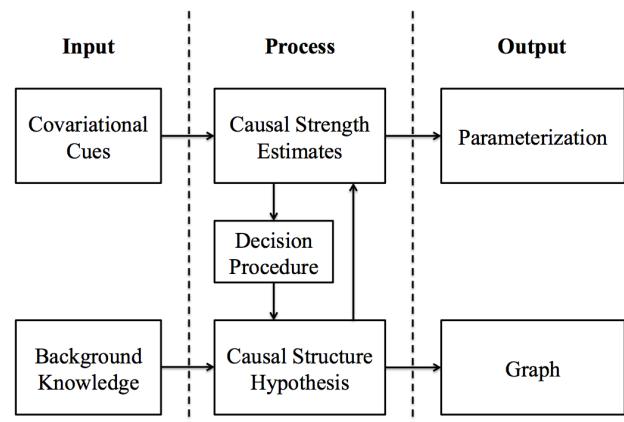

Figure 2: A high-level description of the LPL model

<sup>1</sup> The model can also encode *a priori* belief of definite edge absence, though we omit this complication for reasons of space.

Figure 3: (a) Example local learning context (solid / dashed arrows indicate known / potential causal relations); (b) Causal strength estimates of  $B$  (blue) and  $C$  (red) using five particles per edge

### Causal Strength Estimates

The LPL model generates causal strength estimates for each possible cause-effect pair that is not ruled out *a priori*. That is, for each pair of variables ( $A$ ,  $B$ ), the learner estimates the causal strength of  $A \rightarrow B$  and  $B \rightarrow A$  unless she has prior knowledge about potential edge direction. We assume here that the correct functional form for causal relations is noisy-OR, and so causal strengths are causal powers (Cheng, 1997; Griffiths & Tenenbaum, 2005), though this can change based on background information.

Like the single-effect learning model, we assume that the appropriate scope for learning causal strength includes the potential cause, the effect, and any other definite causes of that effect. For instance, consider Figure 3(a), where the learner believes that  $B$  causes  $E$  and is trying to determine whether  $C$  also causes  $E$ . Unlike the single-effect learning model, however, causal strength estimates for  $C$  are generated by a mechanism similar to particle filters in approximate Bayesian inference, though our “particles” move by associationist learning.

The LPL model initially draws  $n$  particles for each possible causal relation from a prior strength distribution determined by the learner’s background knowledge. The learner’s current beliefs about whether  $C$  causes  $E$  are represented by these particles  $\{V_C^1, \dots, V_C^n\}$ . There is a corresponding set  $\{V_B^1, \dots, V_B^n\}$  of particles for  $B$ . The use of multiple particles enables the model to capture both strength estimates and confidence in those estimates. The mean particle value,  $\bar{V}_C = \frac{1}{n} \sum_{i=1}^n V_C^i$ , is the point estimate of  $C$ ’s causal strength. The average squared deviation of the particles,  $D_C = \frac{1}{n} \sum_{i=1}^n (V_C^i - \bar{V}_C)^2$ , is the learner’s (lack of) confidence: low values of  $D_C$  indicate high confidence.

We define a *layer*  $i$  of particles for an effect  $E$  as the  $i$ -th particle from each known and potential cause of  $E$ . In Figure 3(a), for example, layer  $i$  would be  $\{V_B^i, V_C^i\}$ . A layer of particles is a specific hypothesis about the strengths of all known and potential causes of  $E$ . Each layer is updated

independently after each data point by prediction-error learning. Such learning can be represented schematically as:

$$V_C^{i,t+1} = V_C^{i,t} + \alpha (\text{observed} - \text{expected})$$

The learning rate ( $\alpha$ ) is a free parameter, and *observed* has the value 1 if the effect occurs and 0 if it does not. The value of *expected* is typically the expected value of the effect variable, calculated using the functional form for the cause-effect relation. Many associationist learning models fit this schema, including the classic Rescorla-Wagner model and the causal power estimator of Danks, *et al.* (2003).

The *expected* value is computed separately for each potential cause in a layer. The current structure hypothesis has an influence because *expected* is based on only definite, known causes and the particular target potential cause for that update; other variables are ignored. This restriction reduces the computational demands on the learner, and fits real-world contexts where the learner cannot simultaneously attend to all the potential causes in her environment. If the causes combine as causal powers, then the expected value of  $E$  (for layer  $i$  and potential cause  $C$ ) is:

$$\text{expected} = \prod_{K=\text{present}} (1 - V_K^{i,t-1}) \left( 1 - \prod_{J=\text{present}} (1 - V_J^{i,t-1}) \right)$$

where  $J(K)$  is the set of  $E$ ’s generative (preventive) causes.

Figure 3(b) shows how initial causal strength estimates can change over time. Data were generated by Figure 3(a) with a noisy-OR functional form. At first, the particles are spread widely around zero, representing the learner’s uncertainty in her estimate. As the learner observes more data points, prediction-error learning brings the particles closer to the true parameter values. The layers of particles that are further from the true values will generally have greater errors and thus will shift more towards the true values during learning. As a result, the estimates in different layers converge,<sup>2</sup> representing the learner’s increasing confidence. This process gives no account of structure learning, however, so we turn to that now.

<sup>2</sup> Though they only stabilize around equilibrium values. If the learning rate is based on the learner’s current (lack of) confidence, then true convergence is possible.

## Causal Structure Judgments

The LPL model has a single, definite structure hypothesis at each point in time, which can then be modified by either adding or removing an edge. These modifications are based on a decision procedure applied to the causal strength estimates after each update.

Since an edge with a causal strength of zero is equivalent to no edge, the decision procedure uses a t-test on each set of particles with the null hypothesis that the particles are drawn from a distribution with mean  $\mu = 0$ . The outcome of this test depends on both the particles' mean and deviation. A free parameter  $p_{critical}$  guides the decision procedure. If there is no edge in the graph and the t-test rejects the null hypothesis (i.e., the  $p$ -value  $p$  of the test statistic is less than  $p_{critical}$ ), then an edge is added. If there is an edge present and the t-test does not reach significance (i.e.,  $p > p_{critical}$ ), then the edge is removed from the graph.

If a  $C \rightarrow E$  edge is added or removed, future calculations of *expected* change for *other* potential causes of  $E$ , as those involve only the known causes of  $E$ . Crucially, this form of causal structure learning satisfies: the learner accepts the most plausible structure as a working hypothesis rather than representing and evaluating all possible structure hypotheses (as in standard Bayesian models).

## Other Factors

Temporal information and the data source can influence the interpretation of covariational data, and so are also incorporated into the LPL model.

**Interventions** Given an observation about  $C$  and  $E$ , the LPL model updates the causal strength estimates for both  $C \rightarrow E$  and  $E \rightarrow C$  whenever the model does not yet know which direction the causal influence flows (if any). If  $C$ 's value is instead set by intervention, then one knows that  $C$  is severed from its normal causes. Thus, one should not update causal strength estimates for potential causes of  $C$ . Operationally, if given data about an intervention on  $C$ , the LPL model updates only the  $C \rightarrow E$  particles, and not the  $E \rightarrow C$  ones.

**Temporal Information** Temporal delays between the cause and effect influence contingency learning, though mediated by the learner's expectations (Buehner & May, 2003; Buehner & McGregor, 2006). The LPL model compares the observed temporal difference  $d_{E-C}$  between a potential cause and the effect to the expected temporal difference  $d_{typ}$ . If the learner expects the delay to always be  $d_{typ}$ , then the causal strength estimates update only when that delay occurs. If the learner expects the timeframe of the causal mechanism to be noisy, then the model reduces the salience of  $C$ —captured in the learning rate  $\alpha$ —as a potential cause of  $E$  in proportion to  $d_{err} = d_{E-C} - d_{typ}$ . We define a learning rate  $\alpha'$

that decreases exponentially as  $d_{err}$  increases:  $\alpha' = \alpha e^{-\frac{d_{err}}{s}}$ , where  $s$  is a scaling parameter that determines how sharply  $\alpha'$  drops off as  $d_{err}$  increases.

## Evaluating the LPL Model

### Data

We evaluate the LPL model using data from Lagnado & Sloman (2006). In this experiment, participants had to discover the causal connections between four computers by sending 100 text messages to computer A and observing whether those messages were sent on to other computers. The true causal system is shown in Figure 4, where the arrows represent noisy causal relations. Messages always reached computer A, and the probability of a message being transmitted from one computer to the next was 0.8. Messages never spontaneously occurred.<sup>3</sup> Trial order was randomized both for participants and for modeling.

Figure 4: Causal structure from Lagnado & Sloman (2006)

The original experiment contrasted temporal and covariational information, so there were four conditions that varied the temporal order in which messages appeared. Condition 1 involved no timing information, but conditions 2-4 did (with different delays<sup>4</sup>).

### LPL Model

Participants had no prior knowledge of causal structure, so the initial model was the empty graph (i.e., agnosticism). Connections between the computers were clearly generative, so the model only considered causal strength estimates between 0 and 1. For each possible edge, five particles were drawn from a truncated Gaussian ( $\mu = 0$ ,  $\sigma^2 = .2$ ).

The LPL Model has four other free parameters. The expected temporal delay  $d_{typ}$ , and the temporal scaling parameter  $s$  are not used with simultaneous occurrences (as in condition 1). We thus first determined the values for the learning rate  $\alpha$  and the critical significance level  $p_{critical}$  by maximizing model fit (via a grid search) for condition 1 only. Model fit was based on  $R^2$  values<sup>5</sup> for the proportions, over all possible causal relations  $CR$ , of (a) 1000 model runs that yielded  $CR$ , and (b) experimental participants that

<sup>3</sup> The resulting case distribution ( $N = 100$ ) was: 51 cases with ABCD; 13 AB-CD; 13 ABC-D; 3 AB-C-D; and 20 A-B-C-D.

<sup>4</sup> The messages always appeared in the same order within conditions: A-B-D-C in Condition 2, A-D-C-B in Condition 3, and A-B-CD (C and D simultaneous) in Condition 4.

<sup>5</sup>  $R^2 = 1 - (SS_{err} / SS_{tot})$ , where  $SS_{err}$  and  $SS_{tot}$  are the sum of squared differences between the participant endorsement frequencies and the model proportion or mean endorsement, respectively.

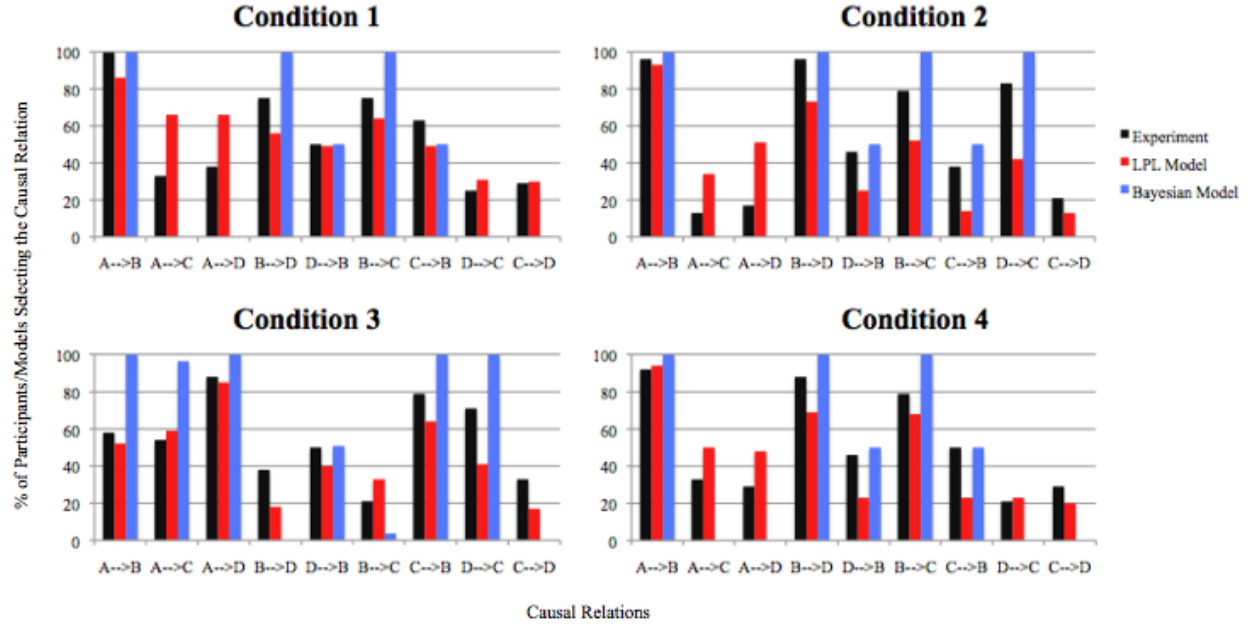

Figure 5: Proportion of causal relation endorsements by the LPL model, Bayesian model, and experimental participants

endorsed  $CR$ . The optimal model fit ( $R^2 = .47$ ) was with  $\alpha = 0.1$  and  $p_{critical} = 7 \times 10^{-5}$ .

These parameter values were used for all subsequent simulations. Model results for conditions 2-4 thus provide cross-validation for those parameter values. We set  $d_{typ} = 1$ , as the natural temporal delay between a computer sending a text message and one receiving it would be one time-step. We then searched and found that  $s = 7$  optimized model fit across conditions 2-4 ( $R^2 = .47$ ).

### Bayesian Model

We compare the LPL model to a standard Bayesian model of causal structure learning. The model used a uniform prior over all possible graphs (cyclic and acyclic) over the four variables. The posterior probability of a graph  $H$  given the  $j$ -th datapoint is:

$$P(H_i | d_j) = \frac{P(d_j | H_i, do(A)) P(H_i)}{P(d_j)}$$

If  $t_V$  denotes the time of  $V$ , then the likelihood is given by:

$$\begin{aligned} P(d_j | H_i, do(A)) &= P(b, c, d, t_B, t_C, t_D | H_i, do(A)) \\ &= P(b, c, d | H_i, do(A)) P(t_B, t_C, t_D | b, c, d, H_i, do(A)) \end{aligned}$$

Participants were told the true parameterization, so we use that distribution to calculate  $P(b, c, d | H_i, do(A))$ . For temporal sequences, the Bayesian model also assumed that

delay probabilities followed an exponential decay function:

$$P(d_{E-C}) = \frac{1}{2s} e^{-\frac{|d_{err}|}{s}} \quad .6$$

This adjustment introduces a new free parameter,  $s$ , that was estimated by maximizing model fit across conditions 2-4 ( $s = 2$ ,  $R^2 = .23$ ). To determine Bayesian model predictions, we assumed that people probability match: the proportion of “Bayesian endorsements” for each causal relation  $CR$  was simply the posterior probability of  $CR$ .

### Results and Discussion

Figure 5 shows the LPL and Bayesian model predictions, as well as the actual participant data.  $R^2$  values for the models for each condition are shown in Table 1.

Table 1:  $R^2$  values for the models

	LPL Model	Bayesian Model
Condition 1	.47	-.03 <sup>7</sup>
Condition 2	.40	.81
Condition 3	.46	-1.01
Condition 4	.59	.36
Overall	.47	.23

The LPL model explains roughly half the variance in participant responses across all conditions, whereas the Bayesian model fit varies widely. Moreover, the Bayesian model does much worse than the LPL model in Condition 1

<sup>6</sup> The probability of a temporal sequence is complicated for cyclic graphs, as one must consider multiple ways to generate a temporal sequence. Technical details are available upon request.

<sup>7</sup> If  $R^2 < 0$  then the mean predicts more variance than the model.

(i.e., with no temporal information), suggesting that the modification of the Bayesian model to allow for temporal delays does not explain the poor fit.

At the same time, both models provide good qualitative fits to the data: the model-participant correlations are  $r = .74$  for the LPL model and  $r = .97$  for the Bayesian model. However, only the LPL model predicts the appropriate variability in the participants' responses. For instance, the data are sufficient in Condition 1 for a Bayesian learner to determine the true causal structure (except for  $D \rightarrow B$  and  $C \rightarrow B$ , about which it is indifferent), and so even probability matchers should exhibit relatively little variation. However, many experimental participants select causal relations that are not part of the true structure, and some omit relations that are. Participants do not seem to be fully rational learners, and the LPL model is able to explain the types of errors that occur.

## Conclusion

The LPL model aims to provide a formal algorithmic model of the mechanisms underlying covariation-based causal structure learning. It provides a computationally well-specified dynamical model that learns directed graphs, and so potentially captures the cognitive mechanisms underlying causal learning. Moreover, this model predicts some of the sub-optimal learning behaviour exhibited by participants. Open questions remain about, for example, the suitability of the t-test-based decision procedure. But the LPL model provides a model that bridges the gap between associationist and rational models of causal learning.

## Abstract

Cognitive modeling is a complex endeavor so it is not surprising that the goals and intentions of modelers are often misunderstood, even by other modelers. To try to clarify this we have attempted to map out the various philosophical and theoretical commitments that one makes when creating a cognitive model or architecture. The goal of this is to avoid misunderstandings between the adherents of different modeling systems and between cognitive modelers and the rest of the scientific community.

**Keywords:** cognitive modeling.

## Introduction

In the 1990s there was movement to contrast mainstream cognitive modeling, which was labeled as *cognitivist*, with alternative approaches which were asserted to represent a fundamentally different paradigm. These alternatives included *situated* cognition, *distributed* cognition, *dynamicism*, *embodied* cognition and *subsumption* architectures. However, Vera and Simon (1993) argued that these theories represented progress and innovation but not an alternative approach. They did this by arguing that critics of the mainstream view had mistakenly assumed that the practices, strategies, and short cuts of mainstream modelers represented their actual philosophical and theoretical commitments. We argue that Vera & Simon's argument was a legitimate response and more generally that philosophical and theoretical commitments cannot be determined solely by analyzing systems and practices associated with a method of modeling. Full understanding requires explicating the philosophical and theoretical commitments of the modeler.

Today all of the alternatives to mainstream modeling discussed in Vera and Simon (1993) are accepted in the main stream. That is to say, they are broadly recognized as important contributions. At this time it would be fair to say that there is no widely accepted, "main stream" approach to modeling. However, despite efforts to understand different modeling systems as alternative approaches, each with their own strengths (e.g., McClelland, 2009) there are still numerous attempts to vilify modeling systems by critics who do not fully understand the goals and intentions of the system creators and users. In our view, the idea that a modeling system can be dismissed based on a principle or a philosophical argument is, in fact, a philosophical mistake.

We argue that pigeon holing modeling systems according to broad philosophical and theoretical distinctions (e.g., *cognitivist* vs. *anti-cognitivist*, *computational* vs. *non-computational*, *representational* vs. *anti-representational*,

etc.) is misleading and counterproductive. In place of this, we advocate a multidimensional approach to characterize modeling systems along numerous dimensions, including the beliefs and motivations of the modeler. Thus in our system, two modelers can use the same computational code but actually have very little in common. Likewise two modelers could use very different codes (e.g., the ACT-R symbolic/subsymbolic code, J. R. Anderson & Lebiere, 1998; and the NENGO spiking neuron code, Eliasmith & Anderson, 2003) and still be completely on the same page. To illustrate this approach we will use the controversial example of the "symbol" throughout the paper, although each dimension can be applied to any modeling construct. Due to limited space we have focused on dimensions that we believe are important.

## AI and Useful fictions

The strong AI hypothesis says that if the functions of the human mind can be correctly simulated on a computer then there will be no difference between the human mind and the computer mind. It is important to note that this hypothesis is silent about the level of abstraction or embodiment required for success. It could involve high level algorithms realized as software, or it could involve a brain made of highly realistic mechanical neurons embodied in a lifelike humanoid robot and raised as a human infant. Therefore, if we apply strong AI to symbols it means that the symbols in a model are a valid way of representing what is taking place in the brain. Alternatively, symbols can be viewed as *useful fictions*. That is, the brain does not process symbols but there is something about the processing of symbols that is analogous to how a brain works and it is therefore useful or expedient to model it in this way.

## Metaphysics

In mainstream western philosophy there are substances and processes that act on the substances. For example, logical formalisms can be used to act on symbolic representations about the state of the world. We will refer to this as substance philosophy. In process philosophy (see Bickhard, 2010; Whitehead & Griffin, 1931) there are no modular substances, only interacting processes. What appear to be substances are temporary emergent properties of ongoing processes. According to Quantum Physics, process philosophy is true for physical objects. For example, the chair across the room is a temporary quantum process not an independent object. Likewise, when you close your eyes and

remember the chair, that memory is a temporary neural process not an object.

Often psychological and linguistic constructs are discussed as if they were actual objects, which leads to confusion because it could mean they are meant as objects (i.e., substance philosophy) or that they are meant as a simplification standing in for a process (i.e., process philosophy). For example, the use of symbols in a model could signify that symbols exist, or it could signify that there is a process that acts as though symbols exist. More generally, a process philosophy view implies that psychological or linguistic constructs in a model should be regarded as abstract proxies standing in for interacting processes – not informationally encapsulated modules as suggested by Fodor (1983). The issue then becomes the relative stability of the processes underlying psychological constructs. Process philosophy is silent on this – neural processes giving rise to psychological constructs could be very stable, resulting in a relatively crisp, well defined constructs; or they could be noisier, resulting in fuzzy and possibly temporary constructs. Determining this, in our opinion, is not a philosophical issue. However, deciding if constructs, such as symbols, actually exist is a philosophical issue.

### Divide and conquer versus unification

The simplicity principle (Chater & Vitányi, 2003) refers to the idea that cognitive phenomena are best modeled in the simplest way. This goal, related to Occam's Razor, is not contentious but becomes less clear when the scope of the phenomena is considered. Newell, in his famous (1973) paper, argued that the phenomena to be explained is the whole brain. Newell (1990) distinguished between micro models (i.e., independent models of different phenomena) and architectural models (i.e., models constrained by the use of a cognitive architecture aimed at describing the whole brain). The goal with micro models is to make them as simple as possible but the goal for models built in an architecture is more complex. The model should be as simple as possible given the constraints of the architecture but the actual goal is to produce an architecture that is as simple as possible across numerous models of different phenomena (including neural phenomena, (J. R. Anderson, 2007a)).

Therefore, from an architectural point of view, *having lots of incommensurate micro models is not useful*, regardless of how simple they are individually. One way around this is to argue that the micro model represents a distinct cognitive/neural module that encapsulates and operates on a particular kind of information (Fodor, 1983). For example, by arguing that there is a distinct symbol based language module, one can ignore issues or problems concerning the viability of using symbols to model other functions of the brain. Therefore, the form of a particular model could reflect the goal of creating a unified architecture, of understanding a distinct module, or of creating the simplest model for a specific phenomenon.

### Reverse and forward Engineering

Reverse engineering involves testing a system, the brain in this case, and working backwards to discover how it functions. Unfortunately, having a model that performs similarly to a human does not confirm that it is a valid model because other future tests may disconfirm it.

However, modeling can also move forward through forward engineering. Forward engineering involves designing a system with the goal of achieving certain functions. Therefore, the goal is to achieve the same functionality that humans have without worrying about doing it in the same way as the brain does. If successful the result would be a system that is roughly isomorphic to how the brain behaves, but does not give insight into how the brain does it. For example, the use of symbols in a model could be due to the belief that symbols behave isomorphically to neural representations.

The difference between backward and forward engineering is also important when evaluating how a model has been evaluated. Generally speaking, attempts to reverse engineer involve careful comparisons to experimental data while attempts to forward engineer involve showing that a model can produce certain functionality. It is important to note that a modeler may also iterate between reverse and forward engineering.

### Epistemic commitments

Epistemic commitment refers to the mechanisms used to build the model. Specifically, we mean it to refer to a commitment to a particular way of understanding and modeling the brain. The debate between proponents of symbol systems and proponents of neural networks is an example of an epistemic debate. The idea motivating such debates is that it is necessary to first get the way of modeling right, otherwise the resulting models will be misleading and ultimately dead ends. This issue has fueled a lot of debate within cognitive science. Examples of different systems are: *symbol systems, neural networks, holographic systems, dynamic systems, spiking neuron models, Bayesian networks, logical systems, grammatical systems* etc. However, it is also possible to view these as tools rather than competing theories, in which case the choice of a particular way of modeling would reflect a pragmatic choice rather than a principled one. Another approach is to view different modeling systems as different lenses for viewing a phenomena in different ways (McClelland, 2009).

Related to this, it is important to note that the word *architecture* is used in two ways. As noted above, it can refer to a system meant to be a unified model of the whole brain, or it can refer to mechanisms for building models that are able to model the whole brain. For example, ACT-R (J. R. Anderson, 1993) is an attempt at creating a unified architecture but it is meant to be a hybrid system and therefore does not embody an epistemic commitment. ACT-R is often described as a production system but this is incorrect as ACT-R has numerous modules that use numerous mechanisms. The use of a production system

module to coordinate the other modules in ACT-R is a commitment to a theory about unification; it is not an epistemic commitment (i.e., a way of understanding the whole brain). In contrast, NENGO (Eliasmith & Anderson, 2003) is a system for building spiking neuron models according to a specific theory about spiking neurons, so the use of NENGO can be seen as an epistemic commitment (i.e., that the whole brain can be modeled in this way).

### **Ontological commitments**

Ontological commitment refers to the way a model is divided into functional parts and their connectivity. There are two reasons why ontological commitments are important. The first has to do with creating unified cognitive architectures. Simply put, a valid cognitive model of the whole brain requires that the functional parts of the model map onto the functional parts of the brain. Although the results of experimental psychology are good for testing models, they may be misleading in terms of telling us what the parts are because their ontologies are defined primarily to make experimentation possible on different psychological phenomena. Unfortunately this does not necessarily tell us what the actual parts are. For example, we remember facts and we remember episodes and these can be treated separately for experimental purposes, but we still do not know if we have separate semantic and declarative memory systems or if they are both products of a single long term memory system.

Another very important issue related to ontologies is cognitive re-use (see M. L. Anderson, 2010). This refers to whether or not our cognitive ontology corresponds to a dedicated neural area. Much of the neural localization work taking place today explicitly or implicitly assumes that it does. However, the cognitive re-use hypothesis is that higher-level cognitive mechanisms and functions can be created by re-using and recombining lower level cognitive mechanisms and functions. If this is true then there are two important consequences: (1) specific brain areas are not dedicated to specific cognitive functions, and (2), the ontology that we should be looking for is at a lower level.

Therefore, modelers may believe that the modules of their system correspond to actual cognitive functions in the brain, and they may further believe that these functions map to dedicated areas of the brain. But having a module in a model does not necessarily mean that they believe either of these things. For example, following the cognitive re-use hypothesis, a module could also represent a function that is created through the interaction of lower level functions under specific conditions. Symbols, or any other construct, can be thought of in either way.

### **System levels**

Allan Newell (1980) proposed that the brain is constructed in the way that computers are engineered, according to system levels. The reason why natural systems would develop distinct hierarchical levels was developed by Simon (1962) but a discussion of this is beyond the scope of this

paper. A system level occurs when the behavior of a complex lower level system can be understood in terms of less complex higher level constructs. For example, in the theory of thermodynamics, the complex interactions of atomic particles can be understood through higher level concepts such as heat and pressure. So a systems level is a real thing (in as much as heat and pressure are real things) but it is important to note that a system level can be weak or strong depending on the relative reduction in complexity produced by the emergent level. A weak system level is leaky, meaning that it is sometimes affected by system levels below it (e.g., Saunders, Kolen, & Pollack, 1994).

The cognitive level is theorized to exist as a systems level above the neural level but there is considerable controversy over whether it exists and if it does, what form does it take? The symbol system hypothesis asserted that the cognitive level is based on processing symbols. Likewise, Chomsky (e.g., Chomsky, 1995) argued that for understanding language, symbols could be divorced from the underlying system that produces them. However, it is instructive to look at exactly what was meant by, "symbol." For Chomsky a symbol is a word, but Newell defined a symbol in terms of distal access (Newell, 1990). Distal access refers to using information that is not local, i.e., information that is transported from another part of the brain. The form of the information or the way it is transferred is not important, therefore Newell's commitment to symbols is completely different from Chomsky's commitment to symbols.

### **Level of Analysis**

Level of analysis is different from system level. Level of analysis refers to analyzing a system at a particular level (e.g., neural, neural groups, networks, symbols). Using a level of analysis may or may not indicate a belief that the level is a systems level. So the use of symbols in a model may indicate a commitment to the symbol system hypothesis, but it could also occur because that level of analysis is useful, without any commitment to the existence of an actual systems level. Also, it is possible to test a model constructed at a higher systems level using a lower level of analysis if there is a theory about how the lower level is related to the higher level. For example, ACT-R models can be tested using a neural level of analysis with an fMRI scan (J. R. Anderson, 2007b). Choice of a level of analysis reflects beliefs about the most effective way of testing a model.

### **Consciousness**

Explaining consciousness is a special case of the strong AI issue that deserves its own section. The question is, could a properly constructed cognitive architecture actually have conscious experiences. From a strong AI point of view the answer is yes, but many people reject this position because they find it hard to imagine. This seems to be due mainly to our subjective experience of qualia.

Qualia refer to the various phenomenal feelings of our conscious experiences. From a modeling point of view

qualia creates a potential problem because thought, emotion, and different types of perception do not feel the same to us; they feel qualitatively different. However, from a cognitive science perspective, and a neuroscience perspective, all qualia arise from information processing that is ultimately realized through the firing of neurons. Since we do not understand what consciousness is or how it creates different qualia from the same underlying mechanism, most cognitive models simply ignore the issue or focus on the correlates of consciousness (e.g., awareness, wakefulness, report ability, etc.).

However, the concept of qualia is important for modeling because it cuts across the board and separates the issue of how information is processed from how it is subjectively experienced. By setting aside the issue of qualia we are implicitly adopting the view that qualia is an epiphenomena; that is, we can model the brain without considering qualia because qualia has no functional significance (Dennett, 1991). This is very convenient since it allows us to model all aspects of the brain as information processing and ignore or put off the problem of explaining why different brain functions feel qualitatively different from each other.

Alternatives to understanding consciousness as an epiphenomena arising from information processing are scarce. Searle (1980) makes his arguments against strong AI by arguing that it leads to absurd consequences or conclusions (the Chinese room is his most famous example), but he does not offer an alternative explanation. Hameroff & Penrose (1996) argue that normal information processing is inadequate to model human cognition and consciousness. They propose that the brain is capable of quantum computing and therefore a valid simulation would require a quantum computer. Although this view is not popular it should be noted as quantum computing is so far the only scientific alternative to normal computing, although, as Penrose concedes, it is still a type of information processing. Chalmers (2010) has argued that if you reject that consciousness arises from information processing, the only option is to adopt some form of dualism.

## Philosophy of science

Some people define science with Popper's (1935) notion of falsifiability. However, although it is in theory possible to falsify cognitive models, it is often the case that the failure of a model leads to changes in the model rather than a rejection of the model. With unified architectures the problem of falsification is trickier because in order to test the architecture, it must be used to build a model of a task, therefore, if it fails, it is unclear if the architecture has been falsified or just the model. Newell (1990) realized this and argued that Lakatos' definition of science (1970) was more appropriate than Popper's for understanding architectures. Essentially, Lakatos defines science in terms of making progress over time, therefore if an architecture or model is improved through testing and refinement so that it explains

more, it can be considered scientific (for a detailed discussion see Cooper, 2007).

It is interesting to note that although some of the criticism directed at testing models comes from Experimental Psychology, Experimental Psychology also fails to follow Popper's model. Specifically, most experiments in Experimental Psychology test for significant differences predicted by a theory, therefore, falsifying the theory would mean showing no significant difference, which would mean accepting the null hypothesis, which is not allowed in the ANOVA or t-test statistics that are generally used. Like modeling, theories in Experimental Psychology are generally altered and not rejected. In both cases it is possible to construe theories that are falsifiable; it is just not very common. The criticism of modeling coming from Experimental Psychology has more to do with statistics. Specifically, Experimental Psychology has a clear definition for defining when two conditions are significantly different. In contrast, the goal for a model is to show that it is significantly similar to a set of data and there is not an agreed upon standard for this (e.g., Roberts & Pashler, 2000), although there are statistical ways to tackle the issue (e.g., Stewart & West, 2010).

Another issue arises from comparisons with Computer Science or Engineering where it is common to evaluate algorithms against each other according to some clear criterion or test set. According to this approach, cognitive models should be compared to see which one explains the data best. This can be done when the models are specifically designed to model the same problem (see Erev et al., 2010 for an example). However, it is not commonly done because models are designed with different goals in mind, therefore a good test set for one might be an inappropriate or poor test set for another. It all depends on the goals and the theoretical framework of the modeler, which is why it is important to be clear about these.

## Conclusion

We have outlined a number of dimensions on which modelers can take different views. Most of them are binary so it is possible to say agree, disagree, or agnostic. This list is not exhaustive, but being aware of where we stand on these issues can potentially avoid a lot of misunderstanding and provide a richer view of the whole modeling enterprise.

We have tried to be neutral in terms of laying out this list but we acknowledge that some people may feel that some of the choices we have presented are invalid. For, example, one could argue that there is no such thing as system levels in the brain. Our point is that we should separate that argument from the evaluation of modeling systems that appear to embody systems levels.

Another issue is the relationship between the different dimensions that we have laid out. People tend to associate sets of beliefs with the use of different modeling systems. Possibly some of the dimensions we described are correlated and logically go together. However, arguments about whether certain dimensions are conceptually related

or conceptually independent should be separated from subjective impressions concerning the co-occurrence of dimensions across the users of different modeling systems.

In order to progress in understanding the various cognitive modeling spaces, the impacts of these and other dimensions need to be further deliberated.

# Reading direction is sufficient to account for the optimal viewing position in reading: The case of music reading

## Abstract

The Optimal viewing position (OVP), the position where word recognition is the best, is biased to the left for English words. Several explanations have been proposed to account for this phenomenon, including the left hemispheric dominance for language, asymmetric information structure of words, and reading direction. However, it is unclear which factor(s) is necessary or sufficient to cause an asymmetric OVP. Using music reading, which shares only the reading direction but not the other two factors with word reading, we show that the OVP for three-note sequences is significantly biased to the left only for expert readers but not for novices. The degree of asymmetry in the OVP curve for music readers increases with individual reading skill, suggesting that their OVP is gradually shifted to the left during the development of reading skills. These suggest that habitual reading direction is sufficient to account for a biased OVP to the left.

**Keywords:** optimal viewing position, word reading, music, expertise, visuospatial bias

## Introduction

It has been well documented that where we look within a word or a sentence determines our reading performance. For example, we recognize English words the best when we fixate to the left of the middle of the words, i.e., the optimal viewing position (OVP) for English words is on the left (also called ‘convenient viewing position’; O’Regan, 1984; Brysbaert & Nazir, 2005). This cannot be explained by the acuity function of our eyes, which is the highest at the fovea but drops symmetrically in the left and right visual periphery (Bouma, 1970). Why is the OVP for English word asymmetric and biased to the left, but not to the right?

Multiple factors have been proposed to account for this phenomenon. The first factor is related to the cerebral hemispheric dominance for language processing (Brysbaert & Nazir, 2005). When we fixate at the left part of a word, most of the letters falls onto the right visual field, where information is initially projected to the left hemisphere. As the language center for most people is in the left hemisphere, word recognition is more efficient when we fixate at the left part of a word as compared with when we fixate at the right part of a word (where most of the word falls onto the left visual field and is initially projected to the right hemisphere). Supporting this account, individuals with

right-hemisphere-dominant language functions have a shifted OVP more towards the end of a word compared with the left-hemisphere-dominant individuals (Brysbaert, 1994; Hunter et al., 2007).

Second, the OVP for words is affected by the information structure of the words. For example, the OVP shifts to the informative position of the words in terms of word identity or meaning, both when the informative part is at the word beginning (e.g., the left part of an English word) or at the end (e.g., the right part of an English word; O’Regan et al., 1984; Deutsch & Rayner, 1999). Also, adding a prefix shifts the OVP towards the word end while a suffix shifts the OVP towards the word beginning (Farid & Grainger, 1996). Since the initial letters are in general more informative about the identity of the word than the last letters for English, the OVP for English words is on the left (Brysbaert & Nazir, 2005; Farid & Grainger, 1996).

Third, the OVP for words can be explained by reading direction. In left-to-right scripts, since the newly arriving information and the next eye movement is on the right, attention is directed more to the right visual field. With years of reading training, perceptual span for reading (the region around fixation from which useful information is extracted) extends further to the right compared with the left (Deutsch & Rayner, 1999). The OVP for English words is on the left because a left fixation leaves most of the word in the right visual field where English readers learn to recognize the word better (Brysbaert & Nazir, 2005). Prior work shows that the OVP for right-to-left scripts (e.g. Arabic) have a more symmetrical OVP (Farid & Grainger, 1996).

While many factors can modulate the OVP for words, which one(s) is necessary and/or sufficient for an asymmetric OVP to occur? In word reading, it is impossible to isolate and test the effect of each factor. Here, we tested whether reading direction alone is sufficient to lead to a left-biased OVP with the domain of music reading. While music reading shares the left-to-right reading direction with English reading, it does not involve strong hemispheric lateralization as experts learn to recruit both hemispheres for music reading (Wong & Gauthier, 2010). In addition, music notation does not follow as strict morphological/

orthographical rules as English text does. Therefore it is unlikely that music sequences in general have an asymmetric information distribution as that in English words<sup>1</sup>. Therefore, music reading allows us to test whether reading direction is sufficient to cause a left-biased OVP.

Here we used three-note sequences and single notes (i.e., the shortest note sequences) as our stimuli. A sequential matching task which did not require music knowledge was used so that we were able to measure the OVP in both experts and novices. In addition, we took advantage of the wide range of music reading ability among the participants to examine how the OVP changes with reading skills. We hypothesized that the OVP is gradually shifted to the left (for left-to-right scripts) when one's reading skill improves. To test this hypothesis, we examined the relationship between the degree of asymmetry of the OVP curve and individual music reading fluency. The hypothesis predicts that the degree of asymmetry of the OVP curve should increase with individual reading fluency.

## Methods

### Participants

Forty-two participants completed the experiment for cash payment or course credits. All participants were right-handed (according to the Edinburgh Handedness Inventory; Oldfield, 1971) except three participants (one intermediate and two novice readers) who were subsequently excluded from data analysis. Twenty-six participants had been formally trained in music reading and were further divided into the expert and intermediate group according to their performance in the perceptual fluency test (see below). The thirteen experts included 12 females and 1 male ( $M_{\text{age}} = 20.2$ ,  $s.d. = 1.69$ ) with 13.4 years of music reading experience on average (ranging from 10-20 years). The twelve intermediate readers included 11 females and 1 male ( $M_{\text{age}} = 21.8$ ,  $s.d. = 4.36$ ) with 9.3 years of experience reading music on average (ranging from 2-17 years). The thirteen novices reported that they could not read music,

<sup>1</sup> There is no consensus and no formal study (to our best knowledge) on the information structure of music sequences. However, probable combinations of sequences (e.g. melodies) are defined by specific music pieces without general morphological, orthographical or phonological structure applicable to all pieces. In this experiment, no musical context, key signatures or accidentals (e.g. sharps or flats) were provided and the sequences only varied along the most common C major scale. In this case, all combinations of the notes are highly probable such that the notes are unlikely more predictable by the left or right part of the sequences. Although some pitch pairs may be more frequent than others in general (e.g. tonal pitch pairs such as 'C' and 'E' are used more frequently compared with tritone pairs such as 'C' and 'F#'), such predictiveness of tone pairs should be largely symmetrical (e.g. 'C' is unlikely followed by 'F#', and 'F#' is also unlikely followed by 'C'). As a result, there is presumably no information structure biased to the left or right for music sequences, at least under the current context.

with 8 females and 5 males ( $M_{\text{age}} = 22.4$ ,  $s.d. = 5.42$ ) and 0.31 years of music reading experience (ranging from 0-3 years). All reported normal or corrected-to-normal vision and gave informed consent according to the guidelines of the Ethics Committee of the University of Hong Kong.

### Stimuli and Design

The experiment was conducted on PCs with the Eyelink 1000 eyetracker (SR Research Ltd, Canada), and Matlab using the Psychtoolbox and the Eyelink Toolbox extension. The eyetracker was positioned on the desk and sampled pupil location at 500 Hz. The tracking mode was pupil and corneal reflection. The standard nine-point calibration procedure was administered at the beginning of the task; the procedure was repeated whenever the drift correction error was larger than one degree of visual angle during the experiment. The acceleration threshold was 8000 degree/s<sup>2</sup> and the threshold for saccade velocity was 30 degree/s. Participants viewed the stimuli at 62 cm from the monitor using a chin rest.

The stimuli were generated with Matlab. 400 three-note sequences were randomly generated, with the constraint that there were no repeated notes within each sequence and no repeated sequences within the set. The sequences subtended about 3° x 3°. Each sequence was paired with a distractor sequence, in which one of the notes was shifted for one step up or down (counterbalanced). Single notes included 11 quarter notes from the note below the bottom staff line (D4) to the note above the top line (G5). They subtended about 1.6° x 3.2° in visual angle. The contrast of the single note stimuli was reduced to half to avoid ceiling performance. The distractor of each single note was the note either one step up or down (counterbalanced).

A sequential matching task was used (Figure 1a). Each trial started when a central fixation was confirmed by the eyetracker. Then, a target stimulus was presented (for 600 ms for sequences and 80 ms for single notes) while participants maintained a central fixation. If the eyetracker detected an eye fixation away from the center, the trial was aborted and an error message was presented to the participant. Next, a second stimulus was presented in the upper or lower visual field at 3.6° from the central fixation. Participants were instructed to saccade to this image and judged whether the two stimuli were identical or not by key press as fast and as accurately as possible.

The critical manipulation was the position of the first target stimulus such that participants fixated at different viewing positions. For sequences, the target was presented at 2° left, 1° left, 0°, 1° right, or 2° right from the central fixation such that participants' central fixation fell onto the far-right, right, center, left, or far-left part of the sequences respectively (Figure 1b). For single notes, the target was presented at 2.5° left, 0° or 2.5° right from fixation. The

dependent measure was the sensitivity ( $d'$ ) and response time (RT).

Trials with different fixation positions were randomized. For sequences, there were 400 trials with 80 trials for each fixation position. For single notes, there were 180 trials with 60 trials for each fixation position. Participants were tested with single notes before the sequences. For each type of stimulus, 20 practice trials with feedback were provided before testing (without feedback).

Figure 1. The sequential matching task (a) and the five fixation positions relative to the note sequences (b). Participants kept central fixation indicated by the black dot. The blue line was marked for illustration purposes and was not actually presented during the test.

### Measure of perceptual fluency

We assessed fluency in music reading with a sequential matching paradigm and used this as an indicator of individual music reading ability since it is more direct and objective compared with other measures such as years of experience and self-rated ability (Wong & Gauthier, 2010). On each trial, a central fixation was presented for 200 ms, followed by a 500 ms pre-mask, and a four-note sequence for a varied duration. After a 500 ms post-mask, two four-note sequences appeared side-by-side, one identical to the first sequence, and the other with one of the notes shifted by one step (with up/down shifts counterbalanced). The task was to select the matching sequence by key press. The presentation duration threshold for 80% accuracy was estimated four times, each with 40 trials, using the QUEST algorithm (Watson & Pelli, 1983). Sequences were randomly generated using notes ranging from the note below the bottom line (a 'D' note) to the note above the top line (a 'G' note). Contrast for all the stimuli was lowered by about 60% to avoid a ceiling effect.

To control for individual differences not specifically tied to expertise with notes, perceptual fluency for four-letter strings was measured in an identical procedure. The strings were randomly generated with 11 letters: b, d, f, g, h, j, k, p, q, t, and y. These letters were selected because they contain parts extending upward or downward, similar to musical notation. To create distractor strings, one of the four letters

was selected (counterbalanced across stimuli) and replaced by a different letter randomly drawn from the set. The string was shown at the same lowered contrast as the sequences.

## Results

One novice and one intermediate reader were excluded from data analyses because their perceptual fluency for notes was  $> 3$  s.d. away from the mean of the rest of the group. Therefore, thirteen experts, twelve intermediate and twelve novice readers were included.

### OVP for sequences

We observed a left-biased OVP for note sequences in experts, which was not found in the other two groups. A  $3 \times 5$  ANOVA with Group (Experts, Intermediates, Novices) and Fixation Position (Far Left, Left, Center, Right, Far Right) on  $d'$  revealed a significant main effect of Group,  $F(2, 34) = 10.2$ ,  $p = .0003$ , in which experts performed better than the other groups in general (LSD tests,  $p < .05$ ). A main effect of Fixation Position was significant,  $F(4, 136) = 18.8$ ,  $p \leq .0001$ , which marginally interacted with Group,  $F(8, 136) = 1.89$ ,  $p = .066$  (Figure 2a).

Figure 2. Matching performance for three-note sequences in  $d'$  (a) or RT (b) with different fixation positions relative to the first presented images.

To increase statistical power, we limited our analyses within the expert and novice groups, as the OVP function for intermediate readers was similar to the other two groups (Figure 2a). Results were similar to the above, except that the Group  $\times$  Fixation Position interaction reached significance,  $F(4, 92) = 3.47$ ,  $p = .011$ . Sheffé tests ( $p < .05$ ) revealed that  $d'$  was similar across positions for novices, suggesting that none of the viewing positions was 'optimal'. For experts, in contrast,  $d'$  was similar between the Far Left, Left and Center positions, while  $d'$  for the Center position

was better than the Right and Far Right positions. Importantly,  $d'$  for the Left position was better than the Right, and that for the Far Left position was better than the Far Right, suggesting the OVP for three-note sequences was biased to the left for experts.

Within the intermediate readers, we did not observe any clear pattern for the OVP function. A one-way ANOVA with Fixation Position on  $d'$  was significant,  $F(4,44) = 4.69$ ,  $p = .003$ . Sheffé tests ( $p < .05$ ) revealed that  $d'$  at the Center position was better than the Far Right but no different from the Far Left. However,  $d'$  was similar between Left and Right positions, and between Far Left and Far Right positions. Therefore we could not conclude that the OVP function for the intermediate readers was biased to either side of the sequences.

For RT, the  $3 \times 5$  ANOVA with Group (Experts, Intermediates, Novices) and Fixation Position revealed a main effect of Group,  $F(2, 34) = 7.36$ ,  $p = .002$ , in which intermediate readers responded significantly slower than the other two groups (LSD tests,  $p < .05$ ; Figure 2b). A main effect of Fixation Position was significant,  $F(4, 136) = 3.08$ ,  $p = .018$ , in which performance at the Far Left position was slower than the Left in general (Sheffé tests,  $p < .05$ ). The interaction between Group and Fixation Position did not reach significance ( $p > .2$ ). When the intermediate readers were excluded, only the main effect of Fixation Position was significant in a similar manner as the above.

### OVP for single notes

A left OVP was observed in intermediate readers but not in experts or novices. A  $3 \times 3$  ANOVA with Group (Experts, Intermediates, Novices) and Fixation Position (Left, Center, Right) on  $d'$  revealed a significant main effect of Group,  $F(2, 34) = 5.41$ ,  $p = .009$ , in which the only group difference was that experts performed better than novices in general (LSD tests,  $p < .05$ ). A main effect of Fixation Position was observed,  $F(2, 68) = 48.8$ ,  $p \leq .0001$ , in which performance was better at the Center than the Left positions and at the Left than the Right positions (LSD tests,  $p < .05$ ). The interaction between Group and Fixation Position was significant,  $F(4, 68) = 4.26$ ,  $p = .004$  (Figure 3a).

We subsequently analyzed the effect of Fixation Position for each group separately. The main effect of Fixation Position was significant in each group, all  $ps < .004$ . For experts and novices, performance was the best at the Center, while performance at the Left and the Right position was similar (LSD tests,  $p < .05$ ), suggesting that the OVP curve was largely symmetrical. However, for intermediate readers, performance at the Center was better than the Left position, which was in turn better than the Right position. In other words, we observed a left OVP with single notes only for the intermediate readers but not for experts or novices.

For RT, the main effect of Fixation Position was significant,  $F(4, 68) = 8.14$ ,  $p = .0003$ , with faster responses at the Center than the other two positions (LSD tests,  $p < .05$ ; Figure 3b). The main effect of Group and its interaction with Fixation Position was not significant ( $F_s < 1$ ).

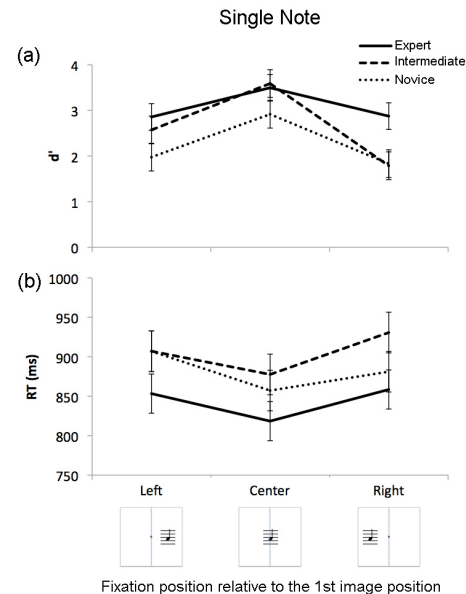

Figure 3. Matching performance for single notes in  $d'$  (a) or RT (b) with different fixation positions relative to the presented images.

### Perceptual fluency

As expected, experts had the highest perceptual fluency for notes, followed by the intermediate group and then by the novices. A one-way ANOVA for Group (Experts, Intermediates, Novices) on duration threshold for notes revealed a significant main effect of Group,  $F(1, 34) = 19.8$ ,  $p \leq .0001$ , where the performance for each group was significantly different ( $M_{Exp} = 316.5$  ms;  $M_{Int} = 680.4$  ms;  $M_{Nov} = 930.9$  ms; LSD tests,  $p < .05$ ). In contrast, duration threshold for letters was similar for all groups ( $M_{Exp} = 186.4$  ms;  $M_{Int} = 207.5$  ms;  $M_{Nov} = 233.9$  ms;  $F < 1$ ), suggesting that experts have a higher perceptual fluency for notes, which cannot be explained by a general perceptual advantage.

### Predicting the degree of asymmetric OVP with perceptual fluency with notes

Does the degree of asymmetry of the OVP curve increase with one's reading ability? We addressed this question by computing the degree of asymmetry of the OVP curve for note sequences using the measure  $d'_{Left} - d'_{Right}$  in each music reader (novices were excluded in this analysis). A significant correlation was observed between the degree of asymmetry and individual perceptual fluency,  $r = -.48$ ,  $p = .015$ ,  $df = 23$  (Figure 4a). A similar trend was observed at

far positions ( $d'_{\text{FarLeft}} - d'_{\text{FarRight}}$ ), though it did not reach significance ( $r = -.27, p = .19$ ). These suggest that the left viewing position of sequences becomes more optimal during the development of music reading skills.

For single notes, the correlation between the degree of asymmetry of the OVP curve ( $d'_{\text{Left}} - d'_{\text{Right}}$ ) and individual perceptual fluency approached significance in an opposite direction ( $r = .37, p = .066, df = 23$ ; Figure 4b). The advantage of left viewing position gradually diminished with better music reading skills.

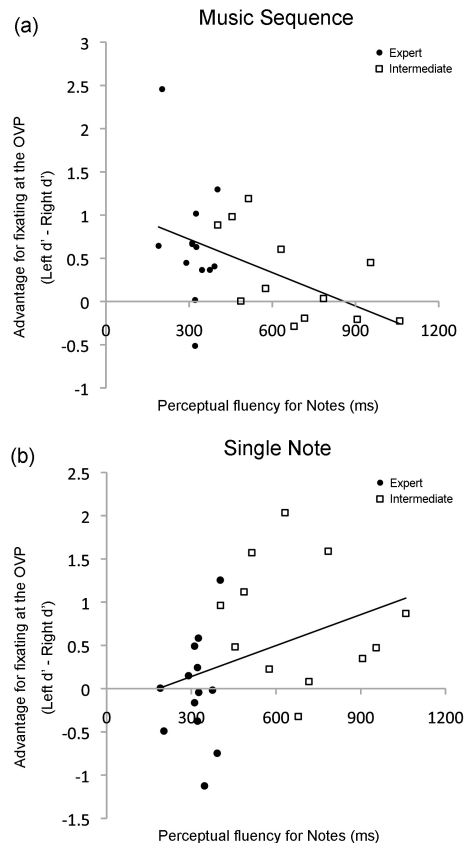

Figure 4. Scatter plots between perceptual fluency for notes and individual degree of asymmetry of the OVP for note sequences (a) and single notes (b).

## Discussion

### For three-note sequences

For three-note sequences, performance was in general the best at the center position, consistent with the highest acuity at fovea. Importantly, we observed an OVP biased to left in music reading experts but not in intermediate or novice readers. Since music reading shares a left-to-right reading direction with word reading but not the hemispheric dominance or asymmetric information distribution, our results suggest that extensive reading experience in the left-to-right reading direction is sufficient to lead to a left-biased OVP in reading.

Our results also suggest that a biased OVP is gradually developed through reading training. For novices, recognition performance is similar across viewing positions and none of the viewing positions is ‘optimal’. When music reading skills develop, the OVP is gradually shifted to the left, suggested by the correlation between the degree of asymmetry in the OVP curve and individual music reading ability. Note that our results cannot be explained by the reading habits of other languages (e.g., Chinese and English for our participants), since all of the participants had the same left-to-right reading habit, while only experts produced a left OVP for music sequences.

While our results suggest that reading direction is a major factor leading to a left-biased OVP in reading, the OVP may also be modulated by other factors, such as the left-hemispheric lateralization for language functions (Brysbaert, 1994; Hunter et al., 2007) and an asymmetric information structure of words (Deutsch & Rayner, 1999; Farid & Grainger, 1996). It is worth noting that different types of word information may become important depending on the OVP task, such as word naming, identification, lexical decision, or word matching tasks (e.g., O’Regan, 1984; Deutsch & Rayner, 1999; Nazir et al., 2004; Farid & Grainger, 1996; Stevens & Grainger, 2003). To evaluate the effect of general information structure of words on the OVP, one should consider whether any observed OVP pattern is solely determined by the characteristics of the specific sets of word stimuli, especially for the distribution of information important for the testing task. In any case, even without an asymmetric information distribution or hemispheric dominance, as in the case of isolated music sequences in the current study, a left OVP can still be observed. It suggests that these are not necessary factors leading to a biased OVP.

### For single notes

For single notes, we observed a left-biased OVP among intermediate readers but not in experts or novices, and the left bias of the OVP decreased with enhanced music reading fluency. There are multiple ways to interpret these findings. First, the performance for experts approached ceiling for all viewing positions (the mean  $d'$  was larger than 3 and the mean accuracy was larger than 90% for all viewing positions) such that potential differences across viewing positions failed to emerge. Indeed, within the experts whose average accuracy for the Left and Right positions < 90%, a left-viewing advantage emerged numerically ( $d' = 2.39$  for Left;  $d' = 2.08$  for Right;  $N = 5$ ), supporting the idea that a ceiling effect prevented a left OVP to be observed among experts. According to this explanation, the OVP for both music sequences and single notes are both biased to the left. Another possible explanation is that the asymmetric OVP effect for single notes simply becomes weaker as in the case of word reading that the asymmetric OVP effect was weaker in short words than long words; Hunter et al., 2007; Ellis,

Young, & Anderson, 1988). This may be caused by a weakened influence from reading direction on short sequences as experts are able to skip them during reading, and such tendency may become larger with better music reading skills.

It has been proposed that reading direction may partly underlie visuospatial asymmetry effects observed in the processing of some visual stimuli, such as identity or affect judgments for faces (Vaid & Singh, 1989; Brady, 2011), or bisection of straight lines (Chokron & Imbert, 1993; see also Kazandjian & Chokron, 2008). Our current results suggest that the visual field asymmetry caused by habitual word reading direction is not generalizable to all domains of object recognition. Specifically, a left-biased OVP for English words is presumably shared by all of our participants who are either English or Chinese-English bilingual readers (O'Regan et al., 1984), while the visual field asymmetry for musical notation varied across groups. In particular, our novices, who did not have music reading experience and thus were most vulnerable to potential transfer effects from word reading habits, did not show a bias that was consistent with the asymmetry observed in word processing. Further studies should investigate why the visuospatial biases stemmed from reading direction generalize to faces and line bisection but not to musical notes.

## Conclusions

In this study, we demonstrate with the case of music reading that a left-to-right reading direction is sufficient to lead to a left-biased OVP in expert reading. The OVP for music sequences may gradually shift to the left in the course of music reading training as reading skills improve. Our failure of observing a left-biased OVP in music sequence processing in novices suggests that the asymmetry effect created by word reading habits is not generalizable to all domains of object recognition. In contrast, it may be a result of learning changes during the development of reading expertise.

## Abstract

Although bilingual language research has increased considerably over the past few decades, there is still much controversy regarding the mechanisms of bilingual language acquisition. The present work aims to provide insights into potential mechanisms of bilingual language learning by utilizing a novel word-learning paradigm in which monolingual and bilingual adults (Experiment 1) and children (Experiment 2) are taught two novel languages either simultaneously or sequentially. Results suggest that bilingual language learning may be occurring in a domain specific manner dependent on learning order, previous language experience, and the participant's age.

**Keywords:** novel word learning; order effects; second language acquisition; bilingualism

## Introduction

Given the increasing prevalence of bilingualism in the world, it is crucial to understand how individuals learn multiple languages and what method of language instruction facilitates learning. Although bilingual language research has increased considerably over the past few decades, there is still much controversy regarding the underlying mechanisms of bilingual language acquisition (BLA). The present paper seeks to shed light on potential mechanisms of BLA by comparing monolingual and bilingual adults (Experiment 1) and children (Experiment 2), who are taught two novel languages either simultaneously or sequentially. This is one of the first papers that experimentally manipulates order of acquisition (OoA) by directly comparing simultaneous and sequential language learning. In addition, the present paper examines the effect of previous language experience on novel word learning by directly comparing monolingual and bilingual participants. Recent research suggests that growing-up bilingual has measurable positive effects on cognitive flexibility (Bialystok, Barac, & Blaye, 2010; Bialystok & Martin, 2004; Bialystok & Viswanathan, 2009; Carlson & Meltzoff, 2008; Kovács & Mehler, 2009; Mezzacappa, 2004) and possibly even novel word learning (Kaushanskaya & Marian, 2009; Yoshida et al., 2011). However, the specific nature of the bilingual cognitive advantage has not been fully addressed. The present work provides insights into these theoretical issues by utilizing a novel word-learning

paradigm in which monolingual and bilingual adults (Experiment 1) and children (Experiment 2) are taught two novel languages either simultaneously or sequentially.

## Previous Language Experience & Word Learning

There is increasing evidence to suggest that monolinguals and bilinguals may employ different strategies or have different biases for word learning. In particular, one such bias is the Mutual Exclusivity (ME) principle. The standard artificial word-learning task that is used to test ME presents a well-known object with a well-known name (e.g., a cup) and a novel unnamed object and then asks participants to select an object, using a novel label (e.g., "Find the dax"). Monolinguals consistently map the novel label to the novel object (Markman, 1989; Markman & Wachtel, 1988). However, bilinguals do not perform as consistently. Many studies have reported that ME may develop later or to a lesser extent in bilinguals (Au & Glusman, 1990; Byers-Heinlein & Werker, 2009; Davidson, Jergovic, Imami, & Theodos, 1997; Davidson & Tell, 2005; Houston-Price et al., 2010; Merriman & Kutlesic, 1993). Others suggest that by 30 months old, bilinguals show ME effects as strong as those of monolinguals (Frank & Poulin-Dubois, 2002). Clearly, there are many important questions that remain in the study of early word learning in monolinguals and bilinguals.

## Order of Acquisition

It is well established that the timing of language exposure can have a substantial impact on how well a language is learned and maintained. Although there are differences of opinion as to the exact age, the general consensus is that there is a sensitive period sometime before puberty, after which language acquisition becomes more difficult (Flege & MacKay, 2004; Johnson & Newport, 1989; Kuhl et al., 1992; Weber-Fox & Neville, 1996; Werker & Tees, 1983; Yamada, 1995). Based on this notion, bilinguals are often classified as being an early or late bilingual, depending on the age of acquisition (AoA) of the second language. There is also evidence regarding AoA effects in experimental studies (Cortese & Khanna, 2007; Morrison & Ellis, 2000; Pérez, 2007) and connectionist networks (Ellis & Lambon Ralph, 2000; Lambon Ralph & Ehsan, 2006; Monaghan &

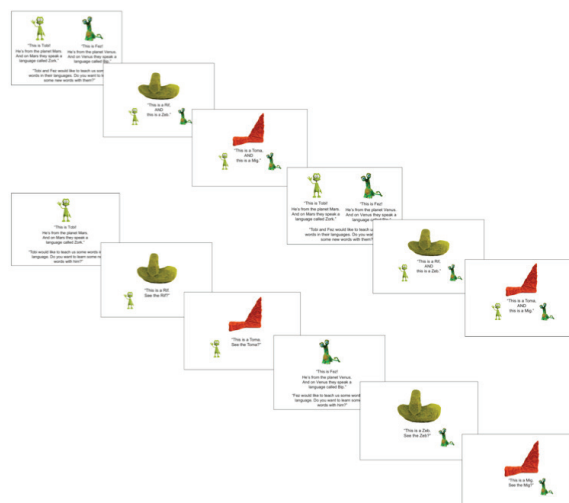

Ellis, 2002) to suggest that early-acquired information is processed faster than later acquired information. Although research regarding AoA and sensitive periods overwhelmingly suggests that learning earlier is better, there is still much controversy regarding the mechanism behind this early advantage.

One explanation that has not been given much consideration is that a more basic mechanism such as order of learning may be responsible for this early advantage (Burling & Yoshida, 2011). Recent experimental paradigms have found that early-learned items are retained better than later-learned items, even when difficulty and age and amount of exposure are controlled (Izura et al., 2011; Stewart & Ellis, 2008). This suggests that AoA effects could actually be due to more basic order effects. The present work further examines this possibility of order effects by comparing simultaneous and sequential learning of two novel languages.

The bilingual literature readily discusses OoA; bilinguals who acquire both languages from birth are referred to as simultaneous bilinguals and those who learn one language before the other are referred to as sequential bilinguals. Simultaneous and sequential bilingualism are even conceptualized as two different mechanisms – Bilingual First Language Acquisition and Second Language Acquisition respectively (for a review see Genesee & Nicoladis, 2007; Paradis, 2007) – suggesting that simultaneous and sequential language learning are qualitatively different. Although these studies provide an important step towards understanding the different types of bilingualism retrospectively, the majority do not experimentally manipulate simultaneous and sequential dual language learning. In addition, BLA is often confounded by the fact that all simultaneous bilinguals are early bilinguals, and many sequential bilinguals are late bilinguals. Given that early learning is thought to be superior, it is important to compare simultaneous and sequential language learning when both occur early. The present work addresses these difficulties by experimentally testing adults (Experiment 1) and children (Experiment 2) who are in the active process of acquiring two new languages in two different mock bilingual environments.

**Figure 1.** Example training trials from the simultaneous condition (a) and sequential condition (b).

**Figure 2.** Sample training design for two word-object pairs in the simultaneous condition (on the top) and the sequential condition (on the bottom) for Experiment 1 and 2.

## Experiment 1

The purpose of Experiment 1 was to determine how the two factors of order of acquisition (OoA) and previous language experience influence word learning in adults. To accomplish this, we utilized a novel word-learning paradigm that imitated a bilingual environment by exposing monolingual and bilingual adults to two novel languages. Participants were randomly assigned to learn these two novel languages either one after the other (Sequential Condition) or at the same time (Simultaneous Condition). Participants were instructed that they would be learning new words from two friendly aliens that were from different planets and spoke different languages. They were then introduced to the aliens and underwent 16 training trials followed by 16 testing trials.

## Participants

Eighty adults ( $M_{\text{age}} = 24.06$  years,  $SD = 4.20$ ) were recruited from the University of Houston in Houston, Texas and were asked to fill out a consent form and demographic questionnaire that included questions about their language history. Based on their responses, participants were identified as bilingual or monolingual and were randomly assigned to either the simultaneous or sequential condition. This yielded four groups of adults: Simultaneous Bilingual ( $N = 21$ ), Simultaneous Monolingual ( $N = 19$ ), Sequential Bilingual ( $N = 20$ ), and Sequential Monolingual ( $N = 20$ ).

Consistent with the Houston population, monolinguals were monolingual English speakers, and bilingual participants represented a variety of language groups, including Arabic-English, French-English, German-English, Japanese-English, Malayalam-English, Mandarin-English, Spanish-English, and Vietnamese-English. Similarly, bilinguals included those who learned both languages from birth, both languages early in life but sequentially, and

second language learners who learned their second language long after their first. This allows the results of the present study to be extended to a broader bilingual population.

## Materials

Sixteen novel word-object pairs were created by assigning each of 16 novel words to one of eight novel objects so that each object had two labels – one in each language. Objects were digital photographs of three-dimensional items created in our lab from craft materials; words were selected from a non-word database (Horst, 2009), produced and recorded by a female native English speaker, and presented auditorily to participants. Sounds were intentionally selected to be as similar as possible across the two languages in order to increase experimental control for the particular question of order effects. Words in each language were matched for length and number of syllables. Alien characters were three-dimensional digital cartoon figures selected from an online graphics database.

## Training

**Sequential Condition** Training Phase 1 included 8 training trials, each of which presented a single novel object on the screen paired with an auditory phrase (i.e. “This is a Dax! See the Dax?”). Each trial lasted 5 seconds with both the auditory phrase and the object presented at trial onset, and the object remaining on the screen for the entire trial. This was immediately followed by Training Phase 2, which continued in the same manner, but with a set of 8 new words for the same objects. By the end of these two phases of training, each of the 8 objects had been on the screen for 10 seconds, and each of the 16 words had been heard twice.

**Simultaneous Condition** Training Phase 1 occurred in the same manner as the sequential condition, except that on each training trial the object was paired with two novel names within the same auditory phrase (i.e. “This is a Dax and this is a Mig!”). Training Phase 2 was an exact replication of phase 1 for this condition. By the end of these two phases of training, each of the 8 objects had been on the screen for 10 seconds, and each of the 16 words had been heard twice.

## Testing

Testing included 16 trials, one for each word-object pair presented during training. Each testing trial consisted of a four-choice forced alternative test that instructed the participant to select a particular object (i.e. “Point to the Dax!”). All target and non-target stimuli had been presented during training. Testing trials were randomized so that word-object pairs from phases 1 and 2 were tested intermixed. Participants received positive or negative auditory feedback on each testing trial based on their response.

**Figure 3.** Experiment 1 results of adults’ learning of novel word-object pairs.

## Results

Overall, adults learned approximately half ( $M = 49.69\%$ ,  $SD = 17.37$ ) of the word-object pairs, and all four groups of adults performed significantly above chance level. See Figure 3 for more details. To determine the influence of order of language acquisition and previous language experience on learning, a fixed effects ANOVA with factors of order (sequential, simultaneous) and language status (monolingual, bilingual) was conducted. Only a main effect of order was found,  $F(1,76) = 5.95$ ,  $p = .017$ , with an advantage for simultaneous learning over sequential learning. No main effect of language status or an interaction of order with language status was found. These findings suggest that regardless of previous language experience, adults learned the languages better when they were presented simultaneously.

## Experiment 2

Results from Experiment 1 suggest that when two languages are taught simultaneously, adults retain a greater number of words than when taught sequentially. In addition, previous language experience did not influence adults’ performance. However, given that children process and learn information differently from adults (Hudson, Kam, & Newport, 2005; Hudson, Kam, & Newport, 2009; Ramscar et al., 2011), and may use different word learning strategies than adults, this raises the question of how order of acquisition and previous language experience influence word learning in children. To accomplish this, we utilized a shortened version of the novel word-learning paradigm in Experiment 1.

## Participants

Seventy-nine children ages 36 to 72 months ( $M_{\text{age}} = 51.78$  months,  $SD = 11.9$ ) were recruited from the local communities and preschools in Houston, Texas. Parents completed a consent form and demographic questionnaire that included questions about their child’s language history. Based on their responses, participants were identified as

bilingual or monolingual and were randomly assigned to either the simultaneous or sequential condition. This yielded four groups of children: Simultaneous Bilingual ( $N = 17$ ), Simultaneous Monolingual ( $N = 23$ ), Sequential Bilingual ( $N = 17$ ), and Sequential Monolingual ( $N = 22$ ). Similar to Experiment 1, bilingual participants represented a variety of language groups and language backgrounds. However, since all participants were 6 years of age or younger, both languages were learned relatively early in life.

## Materials

Stimuli were a subset of the stimuli from Experiment 1 and included 8 novel words and 4 novel objects (each object had two labels – one in each language).

## Procedure

Procedures followed in the same manner as that of Experiment 1, but with a total of 8 training trials instead of 16 and 8 testing trials instead of 16.

## Results

Overall, children learned one-third ( $M = 33.07\%$ ,  $SD = 16.63$ ) of the word-object pairs, and three of the four groups of children performed significantly above chance level. See Figure 4 for more details. To determine the influence of order of acquisition and previous language experience on learning, a fixed effects ANOVA with factors of order (sequential, simultaneous) and language status (monolingual, bilingual) was conducted. No main effects were found, but an interaction effect of order by language status was found,  $F(1,75) = 4.40$ ,  $p = .039$ . This suggests that the effect of order of acquisition on novel word learning was dependent on previous language experience. Post hoc simple main effects analyses revealed that monolinguals scored significantly higher than bilinguals in the sequential condition, but there were no differences between monolinguals and bilinguals in the simultaneous condition.

**Figure 4.** Experiment 2 results of children's learning of novel word-object pairs.

## General Discussion

These findings have implications for our understanding of the mechanisms underlying word learning in general, and how those mechanisms might differ in monolinguals and bilinguals, and adults and children. In particular, our results suggest that word learning may be occurring in a domain specific manner dependent on order of learning, previous language experience, and participant's age.

In regards to the effect of order of learning, adults learned a greater percent of the words in the simultaneous condition than in the sequential condition. This is consistent with previous research regarding sensitive periods (Flege & MacKay, 2004; Johnson & Newport, 1989; Kuhl et al., 1992; Weber-Fox & Neville, 1996; Werker & Tees, 1983; Yamada, 1995), AoA effects (Cortese & Khanna, 2007; Ellis & Lambon Ralph, 2000; Lambon Ralph & Ehsan, 2006; Monaghan & Ellis, 2002; Morrison & Ellis, 2000; Pérez, 2007), and OoA effects (Izura et al., 2011; Stewart & Ellis, 2008), all of which suggest that learning information earlier is better. This simultaneous advantage could also potentially be a result of more distributed learning (see Cepeda, et al., 2006) since information in the simultaneous condition was repeated across two training sessions instead of repeated within a single training session.

However, the effect of order was different for children. In the case of Experiment 2, learning order interacted with children's previous language experience. Monolingual children scored significantly higher than bilingual children in the sequential condition, but there were no differences between monolinguals and bilinguals in the simultaneous condition. Learning order still mattered for children, but the ideal type of acquisition was dependent on their previous language experience.

The effect of previous language experience also differed in children and adults. Experiment 1 revealed no differences between monolingual and bilingual adults in terms of the percent of words learned. However, in Experiment 2, monolingual children performed better than bilingual children in the sequential condition. These results seem inconsistent with previous research that would suggest a possible bilingual advantage for language learning (Kaushanskaya & Marian, 2009; Yoshida et al., 2011). However, the current work essentially entailed associative learning of word-object pairs, whereas previous studies that have found a bilingual cognitive advantage typically involved attentional shifting or competition resolution. Thus, it may be that any bilingual cognitive advantages are highly task specific, and that the current task did not tap into the cognitive skills for which bilinguals typically show an advantage. Future research should continue to evaluate monolinguals' and bilinguals' performance on various types of learning tasks.

Given that the effects of learning order and previous language experience had differential effects in adults and children, it may be that different learning mechanisms are driving bilingual language learning in adults and children.

This is consistent with previous research suggesting that adults and children process information in qualitatively different ways (Hudson, Kam, & Newport, 2005; Hudson, Kam, & Newport, 2009; Ramscar et al., 2011). Additional developmental work is needed to determine how and why these learning mechanisms may change across development.

The present work highlights the potential importance of order in learning and the differential effects that it may have for language learning in monolinguals and bilinguals, as well as in adults and children. As seen here, bilingual language learning may be highly dependent on the specific type of learning environment as well as other factors that were not directly addressed in the present work, such as the relationship between the two languages and the individual's specific linguistic background (Bialystok, McBride-Chang, & Luk, 2005; Cummins, 1979; Müller, 1998; Müller & Hulk, 2001). Although the current stimuli were designed to be similar across languages for purposes of experimental control, this is not akin to a natural language learning environment in which languages are phonologically distinct from one another. Bilingual children in particular may be highly sensitive to such linguistic cues given their experience with these cues signaling which language is being used. These matters merit further investigation to advance general learning theories as well as theories of bilingual language acquisition.

### Acknowledgments

This research was supported in part by a National Institutes of Health grant (R01 HD058620), the Foundation for Child Development, and the University of Houston's Grants to Enhance and Advance Research (GEAR) program. We thank the children and parents who participated in this study.

## **Abstract**

Nisbett et al. (2001) claim that Easterners are more likely to use holistic thinking to solve problems, whereas Westerners are more likely to use analytic thinking. This distinction in cognitive behaviors has often been explained by using a framework based on the fact that Western culture favors independent self-construal (individualist culture) and Eastern culture favors interdependent self-construal (collectivist culture). However, we propose another possible cultural explanation in the distinction between Western low context culture and Eastern high context culture (Hall, 1976). We particularly focus on the difference between the rule-based inference more common in low-context Western cultures and the dialectical inference more common in high-context Eastern cultures, and we argue that rule-based inference using global rules is more adaptive in low context cultures.

Keywords: Culture; Psychology; Reasoning; Cross-cultural analysis.

## **1. Cultural Differences in Cognition**

Nisbett (2003; Nisbett, Peng, Choi, & Norenzayan, 2001) reviewed previous studies on cultural differences in cognition and described the differences in terms of a distinction between analytic and holistic cognition. He argued that individuals from Western cultures are more likely to engage in analytic cognition, whereas individuals from Eastern cultures are more likely to engage in holistic cognition. According to his definition, analytic cognition involves detachment of the object from its context, a tendency to focus on attributes of the object to assign it to a category, and a preference for using rules about the categories to explain and predict the object's behavior. In contrast, holistic cognition is oriented towards context or the field as a whole, attention to relationships between a focal

object and the field, and a preference for explaining and predicting events on the basis of such relationships.

The distinction between analytic and holistic can be described in terms of four dimensions: context-dependent/independent, dispositional/situational attribution, rule-based/dialectical, and stable/changeable views. In terms of the third dimension (rule-based vs. dialectical), people from Western cultures are more inclined to employ rule-based thinking, whereas people from Eastern cultures are more apt to employ dialectical thinking (Buchtel & Norenzayan, 2008; Peng & Nisbett, 1999; Spencer-Rogers, Boucher, Mori, Wang, & Peng, 2009). For example, Norenzayan, Smith, Kim, and Nisbett (2002) reported that, when being asked which group an object should belong to (categorization task), Americans tended to focus on a single property (rule-based inference), whereas Koreans tended to respond based on family resemblance (intuitive inference). Peng and Nisbett (1999) proposed that the cognitive style of Chinese was dialectical, whereas the cognitive style of Americans was rule-based.

## **2. Nisbett's Explanations for the Cultural Differences in Cognition**

Nisbett et al. (2001) explained the distinction between Western analytic and Eastern holistic cognition by using the cultural value dimensions that underlines the individualist and collectivist cultures (Triandis, 1995). They discussed how each style is adaptive within its own cultural type. We regard culture as a hypothetical construct to explain people's behavior as well as to describe social patterns. In the long history of cultural studies, it has been claimed that Western societies have established individualist cultures, whereas Eastern societies have developed collectivist cultures

(Triandis, 1995). The distinction between individualist and collectivist culture is a hypothetical concept proposed to explain the observed differences in behavior, such as that people from Eastern cultures have a stronger preference for sociability and interdependence than do people from Western cultures. Markus and Kitayama (1991) connected this distinction to two kinds of selves. They postulated that, in general, Western cultures foster and favor an independent self, whereas Eastern cultures foster and favor an interdependent self. This distinction refers to differences in how people view themselves: people from Western cultures are likely to view themselves as individualistic, ego-centric, and discrete from society, whereas people from Eastern cultures are more inclined to view themselves as collectivistic, socio-centric, and related to others and to their society.

Nisbett (2003, Nisbett et al., 2001) argued that in a collectivist culture it is adaptive to attend not only to an object itself but also to its context in order to keep the harmony, hence Eastern cultures' holistic cognition is practiced and facilitated. More recently, Nisbett has said he prefers an explanation based on the personal level, in other words on the concept of self-construal (e.g., Varnum, Grossman, Kitayama, & Nisbett, 2010).

The both explanations of Nisbett's are compatible with the results of something called "cultural priming." As already mentioned, it is assumed that Western cultures foster development of an independent self, whereas Eastern cultures promote development of an interdependent self (Markus & Kitayama, 1991). Cultural priming is the mechanism that makes either independent or interdependent self-construal accessible, and the accessible self-construal in turn affects the style of cognition. For example, Kühnen, Hannover, and Schubert (2001) reported that participants who were asked to point out the differences between themselves and their friends or parents (primed as independent self-construal) showed a tendency to process stimuli unaffected by the context (analytic cognition), whereas those who were asked to point out the similarities between themselves and their friends or parents (primed as interdependent self-construal) were more apt to do context-bounded thinking (holistic cognition).

For the distinction between rule-based inference and dialectical inference, Nisbett (2003) adds the importance of cultural tradition. The Western style of thinking has been heavily influenced by the philosophy of Ancient Greece, whereas the Eastern style of thinking grew out of the traditions of Taoism, Confucianism, and Buddhism.

Aristotle's logic was accepted by many Western cultures as it is abstract and universal, whereas Eastern cultures preferred ideas that encouraged and reinforced the harmony of their society. For example, the dual concept of *yin* (negative aspects of the world) and *yang* (positive aspects of the world) form the central essential of Taoism, describing how polar opposites or seemingly contrary forces are in reality interconnected and interdependent. It reflects the tradition of Chinese ontology that the world is constantly changing and shifting, like the balance between *yin* and *yang*, and is full of contradictions. Nisbett concludes that the Chinese view the world as easy to change (e.g., Ji, Nisbett, & Su, 2001), hence abstract rules are not useful for predicting future events or guiding behavior. Nisbett postulates that this is why the Chinese (and thus Easterners) are less likely to use rule-based inference.

In short, these results support the view of cultural psychologists who assume that mind and culture are inseparable. In Western societies, people live in an individualist culture, develop independent self-construal, and thus are more likely to demonstrate analytic cognition, whereas people in Eastern societies live in a collectivist culture, develop interdependent self-construal, and are more apt to demonstrate holistic cognition. This view is summarized as the social orientation hypothesis (Varnum et al., 2010).

However, we see some problems with Nisbett's (2003) explanation. The first is the alleged adaptive nature of Eastern cultures' attention to contextual information. It may well be adaptive to pay attention not only to a target person (object), but to all in-group members (context) in order to maintain in-group harmony in a collectivist culture. However, strictly speaking, this cognitive style is adaptive only in the field of person cognition in a collectivist culture. How can this person cognition be transferred to objects and their context?

Secondly, if Eastern cultures view the world as changeable, the question is whether they try to predict those changes using rules such as *yin* and *yang*. However, Nisbett (2003) takes his interpretation of the Eastern view as fact, and infers that the concept of *yin* and *yang* reflects this view.

### **3. Low Context and High Context Cultures**

#### **3.1 Hall's (1976) Definition**

In order to resolve the problems above, we propose an explanation based on the distinction between low context and high context culture. Hall (1976) introduced a dominant cultural dimension called context to explore the relationship

between culture and communication. His interest was built upon the need to understand the factors that facilitate or inhibit effective communication between individuals from different cultural backgrounds. In explaining this key cultural dimension, Hall and Hall (1990) integrated three main concepts: context, information, and meaning. These three concepts encapsulate context as a system of meaning for information exchanges between groups of people or within a group of people. They further argued that context is embedded in information for the purpose of creating meaning in a message. In other words, without information or context, a message is deemed to be without meaning, therefore insignificant.

With this understanding, Hall's context dimension provides a framework that enables people to comprehend communication forms ranging from the purely non-verbal — hand gestures, body language, facial expressions, and tone of voice (all of which are situational and important in high context cultures) — to the purely verbal, such as written text or spoken words (all of which are informational and important in low context cultures), in order to achieve meaning as the ultimate goal. Zakaria and Cogburn (2010) summarized it thus: high context is known as 'content independent', while low context is known as 'context independent.' There is some evidence that, generally speaking, Western cultures are low context whereas Eastern cultures are high context. For example, Ishii, Reyes, and Kitayama (2003) reported that Americans spontaneously attend more to verbal content than to vocal tone, whereas Japanese attend more to vocal tone than to verbal context. This evidence suggests that Japanese prefer indirect and implicit communication while Americans prefer direct and explicit communication. In their analysis of websites, Würtz (2006) found that websites created by Japanese, Chinese, and Koreans, who are from presumed high context cultures, adopted the visual effects offered by the Internet to convey their messages efficiently to a greater degree than did sites created by Germans, Americans, and Northern Europeans, who are from presumed low context cultures.

In this paper, we propose that the distinction between high context and low context cultures (the L/H context dimension) (Hall, 1976) offers a better explanation for cultural differences in cognition than the distinction between individualism and collectivism (the I/C dimension).

People in a high context culture can interpret messages from others without full descriptions, because implicitly shared information is available to assist the interpretation. For example, if people implicitly share the

idea that a diamond is very expensive and normally used for special occasions, then given the statement 'A presented a diamond ring to B' they may infer that A is proposing marriage to B. Therefore, a speaker can notify you of A's proposal just by saying that A presented a diamond ring to B without further information on marriage. On the other hand, people in a low context culture need explicitly expressed words for communication, because they have little or no implicitly shared information to draw on. Hence, they rely on communication which rests upon direct and explicit communication.

As for the problem of the transference from person cognition to objects, the explanation using the H/L context distinction does not need to rely on transference. According to Ishii et al. (2003) using the H/L context distinction can explain the degree of contextualization, and the degree of how people attend contextual or situational information, which are the first two aspects of the dimension between analytic and holistic cognition. In a high context culture, people's attention is attuned to contextual information because they are accustomed and encouraged to use this information for communication, whereas in a low context culture, people's attention is directed towards the target they want to identify. It is highly plausible that this cultural training affects people's cognition in each culture.

### **3.2 The H/L Context Distinction as an Explanation for Cultural Differences in the Usage of Rules**

The H/L context distinction can also provide an explanation for cultural differences in the usage of rules. The outline of our argument is as follows;

- (1) A global rule is needed when a local rule becomes useless.
- (2) A local rule becomes useless when natural laws and/or social customs are variable.
- (3) Social customs are more variable in low context (Western) cultures than in high context (Eastern) cultures.
- (4) Eastern high context cultures' dialectical inference is not based on global rules but on local rules, while the opposite is true of Western low context cultures.
- (5) Therefore, Western low context cultures are more inclined to use rule-based inference than Eastern high context cultures.

This explanation resolves the problem of why the Chinese, for example, are less inclined to use rules to describe changes that they perceive in the world: because by and large they encounter less variability in their local world and therefore local practice remains useful.

Why have scientific theories been needed for humans? Rules are used to describe the world in terms of natural laws, and to predict consequences. Although they do not give direct suggestions for human action, they are useful in gaining resources (benefits) or avoiding hazards. For example, it is adaptive for people to learn the follow law in a hunter-gatherer society:

*If you go to the river in autumn, you can catch salmon.*

People learn that they can catch salmon every autumn and thus can smoke salmon for eating through the winter. A scientific theory may give an explanation for why one can catch salmon in autumn. If the law is always true, and you can count on the appearance of the salmon every year, theories are not necessary. However, theories which describe the biological mechanisms, habits or behavior of salmon become useful when there are no salmon one autumn. These theories may explain why this situation has occurred and give people some idea how to deal with it: give up fishing, move to another place, or clean the river. Therefore, theories are needed when the environment is not stable, and its natural laws are irregular.

However, we do not assume that the cultural differences in the tendency to seek for a global rule arise from differences in environmental variability between West and East. Rather, we focus on any rule which is used as a cultural coordination device. It takes the form of a deontic conditional, which codifies obligation, permission, and inhibition. For example, Tom fell in love with a girl whose name was Anne when he lived in her country. He wants to marry her, hence he presents her with a diamond ring based on the following belief:

*If Anne wishes to marry Tom, she accepts the diamond which Tom presents her.*

However, it is quite possible that this rule cannot be applied in another culture where people do not share the common belief that a diamond is a marriage gift. If Anne lives in such a society, she may not accept the diamond even if she wants to marry Tom because the rule that Anne knows is as follows:

*If Anne wishes to marry Tom, her father accepts an amount of money from Tom.*

Tom may find out or figure out this rule, give money to

Anne's father, and marry Anne. However, it is more adaptive for them both to know the reasons for the two different rules: that is, the principle of a marriage gift in order to have a happier life. If they know the reasons, they can abandon the old local rules and create new, more global, rules when their child gets married.

We propose that local rules are less useful in a low context culture than in a high context culture. The case of the marriage of Tom and Anne is a typical example: the variability between their backgrounds means that their local rules differ, and acting on them leads to miscommunication. In a nutshell, a global or fundamental rule is necessary when a local rule becomes useless. Cross-cultural studies indicate that people raised in Western cultures prefer more global rules than those raised in Eastern cultures. For example, the results of Norenzayan et al. (2002) cited above showed that Americans preferred to categorize based on formal rules, whereas Koreans inferred based on family resemblance. We propose that the rules used by the Americans are more global than the family resemblance used by the Koreans. Family resemblance consists of set of local rules, and each rule is not true for all members of a category. Spencer-Rodgers, Boucher, Mori, Wang, and Peng (2009) claim that Eastern cultures' dialecticism is naïve, by which they mean that Eastern cultures are more likely to retain some local rules which are contradictory of each other, without resolving the contradiction. Therefore, Eastern cultures' inference is also more local than Western.

The relationship between environmental variability and the necessity of local and global rules are shown in Figure 3. A global rule is not necessary if natural laws or social customs are completely stable. It is needed if the local rule based on natural law or social customs becomes useless. Therefore, the lower the utility of local rules, the higher the necessity of global rules. However, in a completely chaotic situation a global rule is not useful either. Hence, the need for global rules describes an A-shaped curve, as shown in Figure 1. In this figure, focusing on the H/L context distinction, we consider the variability of social customs on the horizontal axis and necessity of a rule on the vertical axis. Social customs are stable in a high context culture, hence it can be located on the left, whereas a low context culture can be located in the middle where social customs are variable to some extent (but not enormously so). However, Nisbett (2003; Nisbett et al., 2001) argues that the Chinese view the world as more changeable than Westerners do, hence he locates the Chinese culture further to the right, where the environment is not stable. This is contradictory with the idea

that Chinese culture is high context, and may therefore be wrong. In short, we cast doubt on Nisbett's argument that Chinese dialectical thinking is based on their view that the world is easily changeable.

Figure 1: Relationship between Variability and Necessity.

### 3.3 Reinterpretation of the Experimental Results on Cultural Priming

How can the results of cultural priming be explained based on the H/L context distinction? Studies on cultural priming by Kühnen et al. (2001) are one reason for considering an explanation based on the I/C dimension. They assumed that participants who were asked to consider the differences between themselves and their parents or friends activated their independent self-construal, whereas participants who were asked to consider the similarities between themselves and their parents or friends activated their interdependent self-construal.

However, it is possible that their experimental manipulation changed the degree of their participants' feeling of shared context with other people. Asking people to consider differences between themselves and their parents or friends may activate their belief that others are different from themselves, and thus they are not able to rely upon the information which they share with others for communication. On the other hand, asking them to consider similarities between themselves and their parents or friends may activate their belief that others are similar to themselves. In other words, the former brought participants to a low context situation whereas the latter brought them to a high context situation.

### 3.4 Accounting for Cultural Diversity

Our more ambitious aim is to connect the L/H context distinction to the explanation for cultural diversity using natural, ecological, and geographical factors. In other words, not only to explain cultural differences in cognition using the L/H context distinction, but to explain the distinctions themselves using natural, ecological, and geographical

factors. The ecological bases for individualism and collectivism have been intensively discussed. The person level of social independence can be intermediate between their group life style and their analytic cognitive style. These studies are known as a socioecological approach (Oishi & Graham, 2010).

We do not deny these discussions. However, the L/H context distinction may be explicable by natural factors as is the I/C distinction. This problem is too large to fully discuss here; we simply point out some factors contributing to the difference between low context and high context culture, which lead people to either rule-based inference or dialectical inference respectively.

The concept of the L/H context distinction is often employed by researchers in human communication. When people perform intercultural communication, both parties are in effect in a low context situation because they share fewer implicit assumptions than when they communicate with someone from their own culture. This idea is a developed version of Langer (1989), who argued that mindful communication is needed for intercultural communication. His concept of 'mindful' communication can be interpreted as explicitly deliberate and careful communication in which people read others' minds when there is a lack of shared implicit assumptions.

Since a low context situation arises when people engage in intercultural communication, a low context culture is more likely to develop in a multicultural environment (one in which people from different cultures keep their own culture but interact with each other). This situation also creates an environment wherein local rules become useless more often.

A geographical factor that reinforces a multicultural environment is when there is no spacious plain which can become the place for a large culturally unified society; societies must therefore remain geographically separated. In order for multicultural conditions to arise and persist, however, these different cultural societies must interact with each other -- for example, if each society is not economically self-sufficient, and can prosper only if it trades with other societies. An ecological factor that enhances the likelihood of trade is an unbalanced distribution of resources among these societies. One place that satisfied all these conditions was Ancient Greece.

## 4. Conclusion: A New Framework

The primary goal of this paper is to propose a possible explanation for cultural differences in cognition, specifically

the analytic cognition practiced by Western cultures and the holistic cognition practiced by Eastern cultures, using the distinction between low context culture in the West and high context culture in the East instead of the distinction between Western individualist culture and Eastern collectivist culture.

Summarizing these points, we propose a framework as shown in Figure 2. In order to explain cultural diversity naturalistically, we give the primary role to geographical and ecological factors. People need rule-based inference in a low context culture, but whether a low context culture (multicultural environment) arises depends on these factors. Our framework is contrasted with that of cultural psychologists (e.g., Nisbett, 2003; Nisbett et al., 2001), who assume that culture and mind are inseparable and emphasize the role of self-construal in culture and cognitive style. By contrast, we propose that culture and *context* are inseparable and, as such, that context has a strong connection to the types of information required in order to draw effective meanings or sense-making into the thinking process.

# “What” versus “How” in Nonvisual Whole-Body Movement

Naohide Yamamoto (n.yamamoto@csuohio.edu)

## Abstract

Dissociable processes for conscious perception (“what” processing) and guidance of action (“how” processing) have been identified in visual, auditory, and somatosensory systems. The present study was designed to find similar dissociation within whole-body movements in which the presence of vestibular information creates a unique perceptual condition. In two experiments, blindfolded participants walked along a linear path and specified the walked distance by verbally estimating it (“what” measure) and by pulling a length of tape that matched the walked distance (“how” measure). Although these two measures yielded largely comparable responses under a normal walking condition, variability in verbal estimates showed a qualitatively different pattern from that in tape-pulling when sensory input into walking was altered by having participants wear a heavy backpack. This suggests that the “what” versus “how” dissociation exists in whole-body movements as well, supporting a claim that it is a general principle with which perceptual systems are organized.

**Keywords:** Perception; action; somatosensory system; vestibular sense; walking

## Introduction

It has been well documented that perceptual systems contain two separable modes of information processing (Milner & Goodale, 1995; Ungerleider & Mishkin, 1982): One is to consciously recognize a stimulus (so-called “what” processing) and the other is to locate it in space and guide action toward it (so-called “how” or “where” processing). For example, a neurological patient who suffered from visual form agnosia was not able to verbally report the orientation of a slot presented in front of her, but was nevertheless able to put a card in the slot in a normal manner (Goodale, Milner, Jakobson, & Carey, 1991). Such dissociation between “what” and “how” (or “where”) has been most clearly established in the visual system, but similar distinctions have also been made in the auditory system (Anourova et al., 2001; Berlin & Zatorre, 2000; Kaas & Hackett, 1999; Maeder et al., 2001; Rauschecker, 1998; Romanski et al., 1999) and somatosensory system (Aglioti, Beltramello, Bonazzi, & Corbetta, 1996; Halligan, Hunt, Marshall, & Wade, 1995; Kammers, van der Ham, & Dijkerman, 2006; Marcel, 2003; Paillard, 1999; Paillard, Michel, & Stelmach, 1983; Reed, Klatzky, & Halgren, 2005; Rossetti, Rode, & Boisson, 1995; Sathian et al., 2011; Sittig, Denier van der Gon, Gielen, & van Wijk, 1985; Van Boven, Ingeholm, Beauchamp, Bikle, & Ungerleider, 2005; Westwood & Goodale, 2003). These converging findings suggest that separate processing of conscious perception and action guidance (or stimulus location) is a general principle with which perceptual systems are organized. However, in virtually all of the previous studies concerning this dissociation within the somatosensory system,

actions were carried out only with body parts, while the body itself remained stationary (e.g., hand or finger movement; for a review, see Dijkerman & de Haan, 2007). In the present study, we explored whether similarly dissociable processes underlie whole-body movements (i.e., walking).

Whole-body movements such as walking present a unique perceptual condition because they encompass not only somatosensory information about motion of each body part but also vestibular information about acceleration and velocity of the entire body. It has been shown that somatosensory perception can be altered in the presence of vestibular inputs (Bottini et al., 1995; Ferrè, Bottini, & Haggard, 2011), which may be due to the fact that somatosensory and vestibular information are processed in an integrated fashion in largely overlapping areas of the brain (Bottini et al., 1994; Fasold et al., 2002; Guldin & Grüsser, 1998; Schwarz & Fredrickson, 1971). For example, Ferrè et al. demonstrated that sensitivity to tactile stimuli can be increased by caloric vestibular stimulation, and they also showed that this perceptual enhancement was specific to the somatosensory system. Findings like this indicate that vestibular inputs affect the operation of the somatosensory system, suggesting that somatosensory processes underlying whole-body movements are not identical to those subserving partial-body actions. Thus, it should not be assumed that similar dissociation between conscious perception and action guidance would be found in whole-body movements as well. Rather, it is an open question that should be addressed empirically.

To address this issue, we conducted two experiments in which blindfolded participants walked along a linear path and indicated the walked distance by using two types of measures: One was driven by a motoric response in which participants pulled a length of tape that matched the walked distance (Philbeck, Woods, Kontra, & Zdenkova, 2010). The other was verbal estimation of the walked distance, which required conscious awareness of how far they had walked. Although we hypothesized that these two measures are based on dissociable processes (i.e., “what” process for verbal estimation and “how” process for tape-pulling), we did not simply look for different patterns of response from them. Even if information about the walked distance was processed in a unified manner for verbal estimation and tape-pulling, they could still yield distinct patterns of data because the post-perceptual transformation required to translate the internal representation of the (already processed) distance information into a behavioral output might be carried out differently for each mode of response (Figure 1A). Thus, a stronger test on whether dissociable processes exist in whole-body movements can be

done by altering sensory input into nonvisual walking and observing how the patterns of response are modulated relative to baseline patterns observed under a normal sensory condition (Foley, 1977; Philbeck & Loomis, 1997). If verbal estimation and tape-pulling were subserved by two separate processes (Figure 1B), it would be more likely that these processes were affected differently by the alteration of sensory input. As a consequence, patterns of response in the two measures would also change differently from the baseline. On the other hand, if a sole process underlay both verbal estimation and tape-pulling (Figure 1A), the altered sensory input would cause some common change in both measures (e.g., both verbal estimates and lengths of tape pulled doubled). These possible changes from the baseline can be observed even if responses in verbal estimation and tape-pulling were generated by different output transformations, because there is no logical ground to postulate that these post-perceptual transformations should also be modified by the sensory alteration; rather, it would be more reasonable to assume that they should remain unchanged.

#### A. Single-process model

#### B. Dual-process model

Figure 1: Schematic diagrams describing two theoretical models of perceptual processing for whole-body movements. (A) A unified process underlies whole-body movements. Responses in verbal estimation and tape-pulling are both controlled by the single process. Different shapes of the arrows representing output transformation indicate the possibility that the same output from the perceptual process can be transformed differently into verbal estimation and tape-pulling. (B) Two separate processes subserve whole-body movements. Responses in verbal estimation and tape-pulling are based on outputs from “what” and “how” processes, respectively.

## Experiment 1

In Experiment 1, healthy adult participants walked without vision under a normal walking condition. It has been shown that verbal estimation of visually specified distance and motoric responses to indicate it (such as tape-pulling) tend to yield similar, if not identical, patterns of response when they are performed by neurologically intact individuals under a normal viewing condition (Philbeck & Loomis, 1997; Philbeck et al., 2010). Thus, it was predicted that similar patterns of data would be observed in the two response modes. They would form a basis with which changes caused by altering sensory input into nonvisual walking (implemented in Experiment 2) were evaluated.

### Method

**Participants** Twelve students (6 males and 6 females, 18–27 years of age) at Cleveland State University volunteered in return for extra credit in psychology courses.

**Materials and Design** Participants walked linear distances of 1–6 m without vision at their own natural pace. A sighted experimenter walked with them while supporting their arm for safety reasons, but no assistance was provided for walking. Participants first walked 3- and 5-m distances, once apiece. They then walked distances of 1, 2, 4, and 6 m six times apiece in random order. These 26 trials were performed in one session. First two trials were used only to acquaint participants with the experimental procedure and therefore excluded from analyses. A long (at least 15 m) and loose measuring tape was used for tape-pulling. For each walked distance, participants made both a tape-pulling response and a verbal estimate. Thus, the experiment utilized a 2 (gender)  $\times$  2 (response mode)  $\times$  4 (walked distance) factorial design. Both response mode and walked distance were within-subject variables. Participants were run individually.

**Procedure** Prior to the experiment, participants were given an opportunity to practice pulling the tape. While standing still, they held one end of the measuring tape and the experimenter extended it so that it was parallel to the floor. A paper clip was attached to the tape at an arbitrary distance (generally in the range of 1–6 m) and participants pulled the tape until the paper clip reached their hands. They used a hand-over-hand motion to pull the tape, rather than pulling it by one hand while holding accumulated tape by the other hand. Participants viewed how the paper clip approached them as the tape was reeled in. This was repeated a few more times with different distances to the paper clip until participants felt acquainted with the tape-pulling procedure.

Following the practice session, participants wore a blindfold and hearing protectors (noise reduction rating: 21 dB) to obscure their vision and hearing. They were then guided to a nearby hallway in which the experiment was conducted. They were disoriented before taken to the hallway, and thus had no clear idea about where they were in the building during the experiment. This manipulation was included because prior

Figure 2: Mean constant and variable errors in estimation of walked distances in Experiments 1 and 2. They are shown as a function of response mode and walked distance. The dashed diagonal lines in panels A and C indicate accurate estimation of the walked distances (i.e., constant error = 0). Error bars represent  $\pm 1$  standard error of the mean.

knowledge about the environment could influence nonvisual distance perception (Philbeck & O'Leary, 2005).

In the beginning of each trial, participants stood at a fixed starting position and held one end of the measuring tape in their preferred hand. The rest of the tape was untangled and placed on the floor. In addition, participants were given a 5-digit random number and asked to remember it until they completed the trial. Because this number was typically retained in memory by rehearsal, this concurrent task was intended to interfere with subvocal counting of steps in walking and draws in tape-pulling that could otherwise be used to aid distance judgement. By discouraging participants from utilizing this counting strategy, their distance perception and its indicators were more based on somatosensory and vestibular information acquired during walking. Participants' accu-

racy in recalling this number ranged from 54.17% to 91.67% in both experiments (mean = 80.03%), suggesting that they attempted to memorize the numbers and it was sufficiently challenging to make the counting difficult. When participants were ready to start the trial, they proceeded straight ahead until they were told to stop at an appropriate distance. They then turned to face the starting position and pulled a length of the measuring tape so that it matched the walked distance. They marked the end of the pulled tape with their fingers and handed it to the experimenter. Subsequently, they gave a verbal estimate of the walked distance by using a distance unit of their choice. Most participants used ft, and a few used m or cm. They were encouraged to be as accurate as possible by using fractions (e.g., .25 m) when necessary. They were also instructed to derive the verbal estimate from the

walked distance, not from the length of tape they just pulled. Finally, participants repeated the 5-digit number, and were guided back to the starting position for the next trial. Participants walked in the same direction in all trials. No feedback was given to participants during the experiment.

**Data Analysis** Lengths of tape pulled and verbal estimates of walked distances were analyzed by calculating constant and variable errors. Constant errors represent how accurately participants indicated the walked distances by tape-pulling and verbal estimation. They were obtained by computing the mean amount of tape pulled and the mean verbal estimate for each walked distance. Variable errors characterized participants' consistency in responding to the same walked distance and were defined by standard deviations of six responses to each walked distance. Constant and variable errors were analyzed separately by split-plot analyses of variance (ANOVAs) with participants' gender as a between-subject factor and response mode (tape-pulling and verbal estimation) and walked distance (1, 2, 4, and 6 m) as within-subject factors. All *F*-tests conducted in this study were corrected for nonsphericity by using Greenhouse–Geisser epsilon when appropriate. Generalized eta squared ( $\eta_G^2$ ) values are reported as effect size statistics (Bakeman, 2005; Olejnik & Algina, 2003).

## Results

**Constant Error** Figure 2A shows mean constant errors in Experiment 1 as a function of response mode and walked distance. Participants generally made larger errors as they walked farther. In addition, tape-pulling tended to yield increasingly larger errors than verbal estimation as the walked distance increased. These observations were supported statistically by the main effect of walked distance,  $F(3,30) = 68.01, p < .001, \eta_G^2 = .60$ , and the interaction between response mode and walked distance,  $F(3,30) = 4.82, p = .049, \eta_G^2 = .056$ . A post-hoc contrast comparing the difference between the two response modes at 6 m against those at other distances had a large effect,  $F(1,11) = 5.17, p = .044, \eta_G^2 = .32$ , suggesting that tape-pulling and verbal estimation produced similar patterns of errors for the most part, except at the longest distance (6 m). Other effects and interactions did not reach statistical significance in the ANOVA.

**Variable Error** Figure 2B shows mean variable errors in Experiment 1 as a function of response mode and walked distance. Participants responded less consistently as the walked distance became longer. Although tape-pulling responses tended to be more variable than verbal estimates, the difference between them was not substantial. Consistent with these observations, only the main effect of walked distance was significant,  $F(3,30) = 16.45, p < .001, \eta_G^2 = .24$ .

## Discussion

As predicted, when participants walked under a normal condition and attempted to specify walked distance, largely comparable responses were yielded from tape-pulling and verbal estimation. These data constituted a baseline against which

findings from Experiment 2 would be evaluated: We manipulated sensory input into nonvisual walking in Experiment 2 to create an altered walking condition and investigated how constant and variable errors would change compared to those observed in Experiment 1.

## Experiment 2

To change sensory input into nonvisual walking, we asked participants to wear a heavy backpack during Experiment 2. Under this altered condition, it was expected that verbal estimation and tape-pulling would yield divergent patterns of response, if they were subserved by dissociable “what” and “how” processes. Given that these two measures mostly produced statistically indistinguishable data in Experiment 1, any differentiation between them would be indicative of the dissociation between conscious perception and action guidance in whole-body movements.

## Method

**Participants** Twelve participants (6 males and 6 females, 21–53 years of age) from the Cleveland State University community volunteered in return for monetary compensation or extra credit in psychology courses. None of them participated in Experiment 1. A new group of participants were recruited for Experiment 2 to avoid demand characteristics in the backpack manipulation. That is, if the same participants were asked to perform the tasks twice with and without the backpack, it would be relatively obvious to them that the backpack was intended to affect their performance.

**Materials, Design, Procedure, and Data Analysis** Experiment 2 was conducted in the same manner as in Experiment 1 except that each participant wore a backpack that weighed between 1/5 and 1/6 of their body weight. This weight range was adopted from previous studies in which the same backpack manipulation successfully induced measurable effects on distance perception (e.g., Proffitt, Stefanucci, Banton, & Epstein, 2003). To determine the appropriate weight of the backpack, each participant's body weight was measured before beginning the experiment. Participants put on the backpack when they were positioned at the starting position in the hallway for the first trial. They kept wearing it until all trials were completed. The backpack weight varied between 10.20 kg and 19.96 kg among participants (mean = 13.58 kg).

## Results

**Constant Error** Mean constant errors in Experiment 2 are plotted in Figure 2C as a function of response mode and walked distance. Compared to Experiment 1, constant errors observed in the present experiment, especially those yielded from verbal estimation, tended to be larger (i.e., participants showed a tendency to indicate the walked distances to be shorter). This change was more prominent in verbal estimation than in tape-pulling, resulting in comparable responses from them throughout the range of walked distance used in the present study. Consistent with this observation, only the

main effect of walked distance was significant,  $F(3,30) = 159.90, p < .001, \eta_G^2 = .68$ .

**Variable Error** Figure 2D shows mean variable errors in Experiment 2 as a function of response mode and walked distance. Variable errors in tape-pulling kept increasing as participants walked farther, just like variable errors in Experiment 1. On the other hand, variable errors in verbal estimation exhibited a qualitatively different pattern: Participants' responses at 6 m were as consistent as those at 4 m. This observation was supported statistically by the significant interaction between response mode and walked distance,  $F(3,30) = 4.98, p = .020, \eta_G^2 = .050$ , and a post-hoc contrast comparing the difference between tape-pulling and verbal estimation at 6 m with those at other distances,  $F(1,11) = 8.13, p = .016, \eta_G^2 = .42$ . The only other effect that was significant in the ANOVA was the main effect of walked distance,  $F(3,30) = 18.15, p < .001, \eta_G^2 = .29$ .

## Discussion

The backpack manipulation exerted two noticeable effects in the present experiment: (1) It caused greater underestimation of walked distance (i.e., larger constant error), especially in verbal estimation at longer distances, which removed the difference between the two measures observed in Experiment 1; and (2) variable errors in verbal estimation did not show further increase beyond the 4-m distance, while those in tape-pulling showed steady increase as a function of walked distance as in Experiment 1. Given that the overall pattern of constant errors exhibited by tape-pulling and verbal estimation was mostly the same as that observed in Experiment 1, much importance may not be attributable to the change in constant errors in Experiment 2. However, the fact that altered sensory input into nonvisual walking only affected response consistency in verbal estimation suggests that processes underlying verbal estimation and tape-pulling are dissociable. Thus, a sign of dissociation between conscious perception and action guidance within whole-body movements was found in the present experiment.

## General Discussion

The present study was designed to explore whether dissociable processes for conscious perception and action guidance can be found in whole-body movements, in which the presence of vestibular information creates a unique perceptual condition. To that end, nonvisually perceived walked distance was assessed by two modes of response: One required explicit recognition of the walked distance (verbal estimation) and the other was primarily controlled by a motor action (tape-pulling). When sensory input into nonvisual walking was altered by having participants carry additional weight, variability in verbal estimates was markedly modulated. On the other hand, variability in tape-pulling responses largely remained unchanged. This suggests that information about walked distance is processed with qualitatively different levels of precision for verbal estimation and tape-pulling,

showing a sign of dissociation between the process underlying conscious perception and that subserving action guidance in whole-body movements. This result builds upon previous findings that the same dissociation is present in visual, auditory, and somatosensory systems (e.g., Belin & Zatorre, 2000; Dijkerman & de Haan, 2007; Milner & Goodale, 1995), supporting a claim that it is a general principle with which perceptual systems are organized.

Although the present study successfully showed the initial evidence for dissociation between conscious perception and action guidance in whole-body movements, several questions are still unanswered. Most notably, it remains to be seen whether the pattern shown by variable errors in Experiment 2 is extendable to longer walked distances. A follow-up study should be carried out by expanding the range of walked distance. The follow-up study should also include a larger number of participants so that Experiments 1 and 2 can be statistically compared; such an analysis was not possible in the present study due to the lack of statistical power. Furthermore, the fact that underestimation of walked distance was exacerbated by the backpack manipulation in Experiment 2 was somewhat counterintuitive: Considering that those participants had to expend a greater amount of energy for walking a given distance, it may be more reasonable to expect that they would judge the distance to be longer, not shorter (Proffitt et al., 2003). Similarly, it is not readily clear why the additional weight increased, not decreased, precision of verbal estimates at the 6-m distance. Further research should be carried out to fully understand these important details.

## Abstract

The ability to decide between multiple fixation targets in complex visual environments is essential for our survival. Evolution has refined this process to be both rapid and cheap, allowing us to perform over 100,000 saccades a day. Previous models for visual decision making have focused on maximizing reward magnitude or expected value ( $EV = \text{probability of reward} \times \text{magnitude of reward}$ ). However, such methods fail to incorporate utility, or happiness derived from reward, optimizing strictly on nominal reward values. We propose an alternative model for visual decision making, maximizing utility as opposed to value under the assumption of a decreasing marginal utility curve. To test our model, we asked 10 UCSD graduate students to participate in an eyetracking experiment where they choose between different fixation targets presented on a brief display. The reward for each target was generated from fixed, predetermined distributions with different variance that was initially unknown to the subjects. The subjects were asked to maximize their reward for each test session within the experiment. Comparing our results with expected value and reward optimizing hedge algorithms, we show that utility-based models more accurately reflect human behavior in visual decision making tasks.

**Keywords:** Visual decision making; risk aversion; utility theory; reward.

## Introduction

Target selection is a complex optimization task that the human visual system must complete thousands of times per day. Assuming a probabilistic, stationary distribution for reward, the problem is directly reducible to the multi-armed bandit problem (Lai & Robbins, 1985; Freund & Schapire, 1997; Auer et al., 2003; Chaudhuri, Freund & Hsu, 2009). Despite the complexity of the problem, an efficient, low-cost algorithm is necessary to permit rapid saccades to be made in the noisy, low-resolution perceptual environment. Previous attempts to model visual decision making involve a probabilistic, reward magnitude framework where the probability of fixation is weighted based on the expected value (EV), defined as the probability of reward multiplied by the magnitude of reward (Milstein & Dorris, 2007; Navalpakkam et al., 2010; Platt & Glimcher, 1999). Depending on the approach, the definition of the probability of reward can be taken either from the traditional economic context as the probability of obtaining a reward upon target

fixation (Milstein & Dorris, 2007; Milstein & Dorris, 2011; Platt & Glimcher, 1999) or from the perspective of noisy sensors, modifying the probability of a target's location given the noise (Navalpakkam et al., 2010). Alternative approaches that have achieved comparable accuracy to expected value strategies include a study on rhesus monkeys by Milstein and Dorris (2011), where they show reward magnitude alone may explain saccadic preparation and reaction time data.

Despite the success of expected value models, there are many real life examples where behavior does not maximize expected value. For example, for many types of large investment (e.g. automobile, home, healthcare), there is a set of insurance policies to reduce risk. Insurance companies sustain themselves by making a small profit while reducing risk for consuming individuals. If it were the case that every individual viewed reward maximization as maximizing their expected value, these institutions would no longer be profitable and would cease to exist. However, there are many instances where individuals are willing to disproportionately sacrifice some of their assets to reduce the probability of an extremely undesirable outcome. As a result, insurance is often viewed as mutually beneficial and is encouraged in many situations. Bernoulli (1738/1954) provided the first examples of deviation from expected value behavior, stating that decisions should be based on an individual's current wealth, with less wealthy individuals being more averse to risky decisions. Brocas and Carrillo (2009) presented a simple illustration where two perfectly rational individuals may come to opposite conclusions in situations of uncertainty due to differences in utility preferences. The goal of our experiment is explore the concept of utility maximization and risk aversion in the context of visual decision making, where decisions are made in quick succession, without much time for the conscious evaluation of value.

We provide an alternative model for visual decision making that attempts to maximize utility, or happiness derived from reward, rather than expected value. In the following sections, we will formally define our model, as well as provide a mathematical justification for why expected value fails to account for behavior with respect to most types of reward. We also compare the predictions of our model with those made by the expected value model and

two well-known machine learning algorithms. Our results show that a risk averse, utility maximization model performs significantly better than the other models at describing human eye movement behavior under all experimental conditions.

### Model Description

Assume that there are  $n$  targets:  $x_i$ , where  $i = 1, \dots, n$ .

- Let  $\pi_{i,l}$  be the probability of encountering target  $x_i$  at location  $l$ .
- Let  $v_i$  be the value for fixating on target  $x_i$ .

The expected value for fixating at location  $l$  can be calculated as follows:

$$EV(l) = \sum_i \pi_{i,l} v_i. \quad [1]$$

However, value alone is often a poor measurement for reward (Bernoulli, 1954; von Neumann & Morgenstern, 1953). This is due to the fact that people tend to have a decreasing marginal utility for most types of reward.

Figure 1: Individuals tend to have a decreasing marginal utility for most types of reward due to priorities in reward allocation (see text). Note that for decreasing marginal utility, the utility derived from doubling the value of reward is less than twice the utility of the original value:  $u(2v_i) < 2u(v_i)$ .

Intuitively, decreasing marginal utility arises from how consumption of reward is allocated. The first units of a reward such as money tend to be spent towards essential necessities, while later units tend to be used on luxury goods. Similar arguments could be made for other rewards such as food, shelter, and material goods. Figure 1 depicts a standard decreasing marginal utility curve.

One implication of holding a decreasing marginal utility curve is that the risk averse decision will frequently maximize utility. For example, Figure 2 shows that under the decreasing marginal utility assumption, an individual will always prefer an action that generates a guaranteed

Figure 2: A property of the decreasing marginal utility curve is that individuals should demonstrate risk averse behavior in their decision making. Despite having identical expected values, a fair chance between  $v_a$  and  $v_b$  yields  $u^*$ , which is less than the utility provided by  $0.5(v_a + v_b)$ , which yields  $u^*$ . Note that the choice between  $v_a$  and  $v_b$  has greater variance than the single point,  $0.5(v_a + v_b)$ .

reward to one which provides a fair gamble between two outcomes that preserves expected value. This result generalizes: individuals with a decreasing marginal utility for reward should always prefer the choice with lower variance, given options of equal expected value.

Replacing value ( $v_i$ ) with utility  $u(v_i)$ , we obtain the following equation for expected utility:

$$EU(l) = \sum_i \pi_{i,l} u(v_i). \quad [2]$$

The goal of the subject is to find the location in the scene that contains the target which maximizes expected utility. Therefore, the objective function for maximizing utility is:

$$f = \operatorname{argmax}_l \sum_i \pi_{i,l} u(v_i). \quad [3]$$

To model  $u(v_i)$ , we note that it is monotonically increasing, but has a decreasing slope leading to diminishing returns with increased reward. For our model, we represent the curve using a natural logarithm because of its simplicity and because it shares the same properties as the utility curve. It is important to note that no two individuals hold the same utility function for reward, and the natural logarithm reflects a hypothetical utility function of the average individual.

The new objective function thus becomes:

$$f = \operatorname{argmax}_l \sum_i \pi_{i,l} \ln(cv_i + 1) \quad [4]$$

where  $c$  is a constant value reflecting the magnitude of risk aversion. In our experiment,  $v_i$  is a value that must be learned by the subject for each experimental phase.

Based on feedback, in each trial we approximate  $u(v_i)$  as a weighted average across past observed rewards,  $\ln(cr_1 + 1), \ln(cr_2 + 1), \dots, \ln(cr_t + 1)$ . Similarly,  $v_i$  is approximated by the weighted average of the observed rewards sequence  $(r_1, r_2, \dots, r_t)$ . Since the targets in our experiment are visually dissimilar,  $\pi_{i,l}$  becomes close to 0 or 1 depending on the target. This allows us to approximate  $\pi_{i,l} \in \{0, 1\}$  and simplifies our calculation.

## Experimental Methods

### Subjects

Ten naive subjects participated in the experiment after providing informed consent. All subjects were right-handed graduate students from the University of California, San Diego Computer Science and Engineering department.

### Experimental Procedure

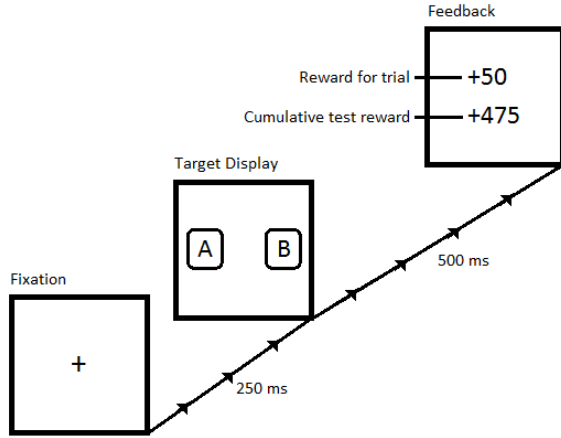

Figure 3: The basic experimental setup. At start of every trial, subjects were asked to hold a central fixation for 250 ms before being presented the target display. Once the targets are presented, the subject must make a saccade to one of the targets within 500 ms, when feedback is displayed. If no decision is made within the 500 ms, the subject receives no reward for the trial and is notified that they must make their decision faster. Subjects are permitted to spend as long as they wish on the feedback screen prior to starting the next trial to make adjustments to their strategy.

We model our experiment using similar parameters to those used in Navalpakkam et al. (2010). At the beginning of every trial, subjects were asked to indicate they were ready by fixating at a center fixation point and pressing the “enter” key on the keyboard. Each trial begins with a central fixation ‘+’ presented for 250 milliseconds. Subjects indicate their choice by saccading to one of the targets. Then, subjects were presented with an image containing two targets labeled ‘A’ and ‘B’ for 500 milliseconds. Figure 3 provides an illustrated description of each trial.

Targets in the experiment appeared at 7 degrees eccentricity from the central fixation point, and were horizontally aligned. The target stimuli were 1.8 degree in height and was each encompassed by a  $3.6 \times 3.6$  degrees square border. The location where each target appeared was randomly generated from trial to trial. Subjects viewed the display on a 19-inch cathode ray tube (CRT) monitor at a distance of 30 inches from the screen.

The experiment consists of an initial training phase and three test phases of 50 trials each. In the training phase, the rewards for the two targets were drawn from discrete uniform distributions,  $U[0, 50]$  and  $U[50, 100]$ . Subjects were required to learn which target yielded the higher reward and fixate on that target for at least 75 percent of the training trials before being allowed to proceed to the test phase. This was done to ensure the subject was accustomed to making quick and accurate saccades while wearing the eyetracking device. Subsequently, each test phase consisted of two targets of equal mean, but different variance.

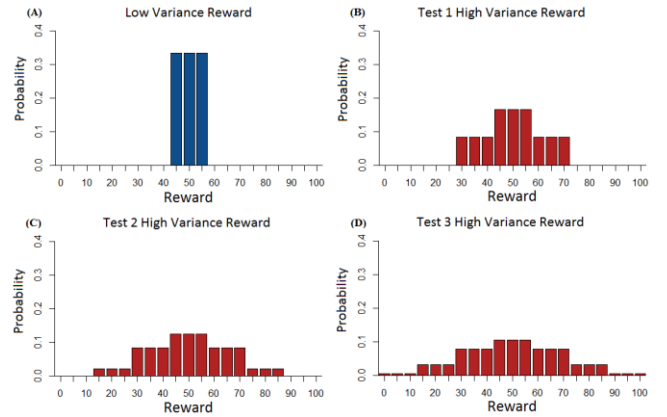

Figure 4: The distribution of target reward for each test. Of the two targets, the lower variance target (4A) was kept constant for all three tests, while the distribution of the higher variance targets (4B), (4C), and (4D) changed for Tests 1, 2, and 3 respectively.

The reward for each target was generated from the distributions described in Figure 4. For each test, the higher variance target’s distribution was adjusted, while the lower variance distribution was kept constant across all of the tests. Subjects did not know the identity or probability distribution of the target at the beginning of each trial or test phase in the experiment. They were instructed to learn the distributions and maximize their reward for each test phase.

We used an Eyelink 1000 eyetracker from SR Research to record the subjects’ eye movements. At the beginning of each test, the eyetracker was recalibrated using a nine-point calibration across the edge and center of the display.

### Modeling Procedure

Performance for each model was measured by the percentage of trials in which the model matches the human

fixation decision. For each trial, the utility-based risk averse model picked the location that maximized the objective function described in Equation [4], while the expected value model maximized  $\text{argmax}_l \sum_i \pi_{i,l} v_i$ . We chose the constant  $c$  from Equation [4] by binary search across the  $[0, 10]$  interval, finding the value of  $c$  that best predicted the human subject data. However, the results were not sensitive to the exact choice of  $c$ .

Every model prediction was compared with the decision made by the subject. Updates to both models (i.e. running averages to  $v_i$  and  $u(v_i)$ ), were done based on the experimental feedback provided to the subjects for each individual trial, as if the model had made the same choice as the subject. In addition to the greedy algorithms, where the model decision is always the one that maximized the objective function, we compared the performance of three policies that include exploration of less-valued alternatives:  $\epsilon$ -greedy, decreasing  $\epsilon$ , and softmax (Sutton & Barto, 1998). We tested epsilon and softmax temperature values of 0.05, 0.10, and 0.20. The exploration algorithms may be summarized subsequently as follows:

#### **$\epsilon$ -greedy:**

**Initialize  $\epsilon$**

*For every trial*

**Generate** random number  $r \in [0, 1]$

**If**  $r > \epsilon$

Take action maximizing the objective function

**Else**

Randomly generate action from uniform distribution

#### **Decreasing $\epsilon$ :**

**Initialize  $\epsilon$ , dec\_rate** =  $\epsilon / (\text{num\_trials} - 1)$

*For every trial*

**Generate** random number  $r \in [0, 1]$

**If**  $r > \epsilon$

Take action maximizing the objective function

**Else**

Randomly generate action from uniform distribution

**Update  $\epsilon = \epsilon - \text{dec\_rate}$**

#### **Softmax:**

**Initialize  $\tau$**

*For every trial*

**Generate** action  $i$  based on probability density:

$$\frac{e^{Q_t(i)/\tau}}{\sum_{j=1}^2 e^{Q_t(j)/\tau}}$$

where  $Q_t(i)$  is the running average of reward for choosing  $i$ .

Aside from comparing prediction performance against expected value, we also compared our results against two well-known machine learning algorithms, Hedge (Freund & Schapire, 1997) and Normal-Hedge, (Chaudhuri, Freund & Hsu, 2009) from the multi-arm bandit problem literature. Both algorithms are designed to maximize reward, given a single parameter value ( $\beta$  for Hedge and  $c_t$  for Normal-Hedge). Before we continue, it is

important to take note of one subtle difference in the objective function of the multi-armed bandit problem with our problem. The objective function of the multi-armed bandit minimizes regret (defined as the difference in reward between the ideal and the chosen action) as opposed to maximizing accumulated reward. To address this, we linearly transformed the reward obtained to range from  $[0, 1]$  and compute the loss of each action as the difference,  $1 - \text{reward}$ . In our Hedge implementation, we tested the entire range of temperature values  $[0, 1]$  in increments of 0.05. We find the best temperature setting to be  $\beta = 0.05$ , and use it for our analysis. For Normal-Hedge, the algorithm is self-adapting around a variable constraint  $c_t$  (note this variable is unrelated to the variable  $c$  from Equation [4]). We solve for  $c_t$  using line search as recommended by the authors. A detailed description of the algorithm as well as the proof on performance bounds may be found for Hedge in Freund & Schapire (1997) and Normal-Hedge in Chaudhuri, Freund & Hsu (2009).

In all our models, we excluded two subjects from our experiment as their data lay beyond two standard deviations from the mean number of saccades to the lower variance target. Note that we did not purposely remove risk seekers as this is equivalent to removing data with respect to the higher variance target due to the fact that there are two targets. Of these, one of the subjects was removed because he systematically fixated only at the target that appeared on the left side of the display, regardless of the identity of the target.

To address potential location bias concerns in making saccades, we recruited only right-handed subjects for our study. In addition, we tested our models with and without two location-based prior probabilities obtained from subject responses. The priors were the probability of fixating at each potential target location, and the probability of returning, given a previous saccade to the same location on the previous trial. In all of our models, there was no significant change in performance when we incorporated the priors under a Bayesian setting. For this and all model comparisons used in this paper, we used a paired t-test to compare the performance between models.

## **Results**

### **Behavioral Data**

The results of the human experiment are presented in Figure 5. For each test phase, we maintained a record of the number of saccade decisions to each target. The reward distribution for higher variance target in Tests 1-3 shared the same mean, but differed in variance as shown in Figure 4 (B-D) respectively, so the utility for these choices will increase. The lower variance target maintained the same distribution for all three tests. In Test 3, the subjects showed significantly risk averse behavior ( $p = 0.0321$ ), choosing the lower variance target 54.8 percent of the time. As the difference in variance between the targets decreased, subjects

Figure 5: The results from the human experiment. The gray line represents indifference between the two targets. The reward distribution for the higher variance target in Tests 1-3 shared the same mean, but differed in variance as shown in Figure 4 (B-D) respectively. Of the three tests, subjects showed significant risk averse behavior in Test 3 (the test with greatest difference in variance between the two targets), where they chose the lower variance target 54.8% of the time.

became increasingly indifferent between the two targets. Subjects in Test 2 chose the lower variance target 54.2 percent of the time ( $p = 0.0861$ ), while subjects in Test 1 chose the lower variance target 50.8 percent of the time ( $p = 0.621$ ).

### Choosing a Value for $c$

Recall from Equation [4] in the model description where a constant,  $c$ , was included to allow for fine-tuning of the magnitude of risk-averse preferences. One interesting, and perhaps surprising result is that most reasonable settings of  $c$  outperform the expected value model in predicting human behavior. For this reason, we simply chose a local maximum using a binary search across positive values of  $c$ . Exceptions to this include  $c = 0$  (when the strategy reduces to random) and extremely large values of  $c$  (when most rewards share approximately the same value).

### Comparison with Expected Value

We simulated the expected value and utility-based risk averse strategies for 100 simulations ( $c = 2.48$ ) using greedy,  $\epsilon$ -greedy, decreasing  $\epsilon$ , and softmax exploration functions (Sutton & Barto, 1998). Our results show that all non-greedy algorithms perform significantly worse than their greedy counterparts ( $p < 0.001$ ). Simple exploration strategies yield poor performance because although they are capable of accurately capturing the probability of exploration, they fail at correctly predicting the trials on which they occur. As a result, since the probability of performing a reward maximizing action for any given trial is greater than the probability of

Figure 6: A comparison of the model fits between the greedy expected value and greedy utility-based risk averse (RA) strategies in predicting human data. In all three test conditions, the utility-based risk averse strategy significantly outperformed the expected value (EV) strategy for  $T = 100$  simulations ( $p < 0.001$ ). The gray dotted line represents chance performance, while the red dotted line represents fit obtained by always choosing the lower variance target (an omniscient model). Given a limited history of reward, the subject may choose the higher variance target as a result of a greedy action. Performance above the red dotted line suggests that the algorithm was fairly accurate its prediction of when the subject chose to take such greedy action as opposed to exploring the other option.

exploration, the greedy version of the algorithm will significantly outperform their exploration counterpart.

Figure 6 compares the utility-based risk averse strategy with the expected value strategy in predicting human behavior. The results show that although both models perform significantly above chance, maximizing across utility significantly outperforms value maximization ( $p < 0.001$ ) for all three test conditions. The red dotted line provides a benchmark for how much performance may be obtained from a strategy defined by choosing only the lower variance target. Note that this is an overprediction, since at the beginning of each test phase, the subject does not know which of the two targets holds lower variance (or even the value of their reward).

### Comparison with Hedge

We compare the fit of the utility-based risk averse strategy with two well-known algorithms for solving the multi-armed bandit problem from machine learning. We choose to implement hedge algorithms over an alternate strategy, Exp4 (Auer et al., 2003) due to its superior performance under conditions where the reward distribution is fixed (the reward probability distributions are fixed for our experiment as shown in Figure 4). We test twenty values for the temperature value ( $\beta$ ) in Hedge and present the result for the optimal setting,  $\beta = 0.05$ . For Normal-Hedge, we find the constraint,  $c_t$ , via line search as recommended by the authors. Figure 7 shows a summary of our results. In all three test conditions, the

utility-based risk averse strategy significantly outperforms hedge algorithms under their optimal settings ( $p < 0.001$ ).

Figure 7: The results comparing the performance between the utility-based risk averse strategy with Hedge (H) and Normal-Hedge (NH) algorithms on predicting human data. In all three test conditions, the utility-based risk averse strategy significantly outperformed the Hedge and Normal-Hedge strategies for  $T = 100$  simulations ( $p < 0.001$ ). The gray dotted line represents chance performance, while the red dotted line represents performance obtained from only choosing the lower variance target.

## Discussion and Future Work

Our work shows that by constructing models from a utility maximization standpoint, we are able to make predictions regarding human behavior that would otherwise be impossible in situations involving risk. Previous models in saccadic prediction involved a direct integration of the probability and magnitude of reward, ignoring risk derived from variance in reward distributions. In this paper, we present evidence suggesting the importance of such parameters when modeling visual decision making. Our findings show that under conditions of uncertainty, the human visual system takes a risk averse approach, taking account of the variance of the reward distribution in addition to the mean.

However, the current utility-based risk averse model does not address all questions that arise with the incorporation of risk. In particular, the work does not address issues raised from prospect theory (Kahneman & Tversky, 1979; Tversky & Kahneman, 1992; Kusev et al., 2009). For example, in the context of the experiment, there is no loss associated with viewing any target, and thus the asymmetry between loss and gain perception could not be modeled. Likewise, there are many situations where risk seeking behavior is exhibited and is the utility optimizing choice. While both conditions may arise in vision, prospect theory could not be modeled under the current experimental framework, and risk seeking behavior would require a change in the shape of the utility

function. However, despite these limitations, we believe that the current work presents a starting point for analyzing visual decision making under uncertainty.

# Splitting Visual Focal Attention? It Probably Depends on Who You Are

Jit Yong Yap (yapjityong@gmail.com)

## Abstract

Research evidence now suggests that the deployment of multiple attentional foci in non-contiguous locations (i.e., splitting visual focal attention) is possible under some circumstances. However, the exact circumstances under which focal attention might ‘split’ have not been well understood. The present study is the first in the literature to examine the possibility that ecological differences arising from our increasingly media-saturated environment may result in individual differences in the capacity to demonstrate splitting focal attention. Results suggest a significant relationship between the behavioural preference for consuming multiple media forms simultaneously and the capacity to employ a split mode of attention.

**Keywords:** Ecological differences; splitting focal attention; media multitasking

## Introduction

In visual attention research, whether the focus of attention can be divided is an issue of debate. Several authors espouse the view that the focus of attention is unitary and indivisible in nature (e.g. Eriksen & Yeh, 1985; McCormick & Klein, 1990; Pan & Eriksen, 1993). In order to account for the processing of multiple visual stimuli in different spatial locations, two different theories have been proposed. The *serial shifting theory of attention* suggests that the focus of attention rapidly shifts between different locations (Eriksen & Eriksen, 1974; Posner, 1980), whereas the *zoom lens theory of attention* suggests that the focus of attention is adjusted in size to accommodate multiple locations (Eriksen & St. James, 1986).

However, there is a growing body of evidence which supports the possibility of split attentional foci, or allocation of attention to noncontiguous regions (for review, see Jans, Peters, & De Weerd, 2010; cf. Cave, Bush & Taylor, 2010). For instance, Awh and Pashler (2000) presented participants with a 5 x 5 stimulus array and tasked them with identifying two targets following the onset of cues (validity = 80%). Results showed a strong accuracy advantage at cued locations that did not apply to targets appearing between cued locations, which suggest a divided focus of attention. In their appraisal of the current literature, Cave, Bush and Taylor (2010) concluded “the weight of evidence suggests that some form of split attention is possible in some circumstances”.

With the focus on establishing the possibility of split attention, there has been little research into the exact circumstances under which split attention might arise. This was the crux of a recent study by Lim and Lee (2011), who hypothesized that adoption of a unitary or split mode of attention could be a strategic choice made by the visual system, depending on whichever was the least effortful means of extracting target information from a particular visual presentation. To test this, Lim and Lee employed a modified version of the paradigm used in McCormick, Klein and Johnston (1998).

In the double cue condition of the original study, boxes 10° to the left and right of a central fixation point were used to cue the subsequent onset of a target dot. The target could appear inside either box, or between a box and the central fixation. Participants were tasked with responding to the target once it appeared in their visual field. Results showed that reaction times (RTs) for targets in cued locations (i.e. in boxes) did not differ from those that appeared in irrelevant locations (i.e. outside boxes), which was interpreted as indicative of a unitary mode of attention (See Figure 1).

For their modified version of the double cue condition, Lim and Lee introduced a vertical wall positioned in the centre of the visual display with the intent of preventing a single locus of attention from encompassing both boxes. It was believed that this would incentivize a split mode of attention and, in contrast with McCormick et al. (1998), give rise to RTs for targets in irrelevant locations that were

Figure 1. Predicted result trends, depending on mode of attention employed in double cue condition (McCormick et al., 1998).

slower than those in cued locations. Most intriguingly, while results revealed the expected trend, this was regardless of the presence or absence of the vertical wall. In other words, participants showed the capacity to split attention for both the experimental and control conditions – a contradiction of McCormick and colleagues' findings.

To explain this contradiction, Lim and Lee point towards the 10-odd years that have passed between the two studies. While this may not seem much in absolute terms, the 21<sup>st</sup> century has seen an exponential increase in the prevalence of digital devices in modern society. Compared to the undergraduates of 1998, those in 2011 would have grown up in a far more media-saturated environment with simultaneous exposure to multiple rich streams of information being a common occurrence (Ophir, Nass & Wagner, 2009). Studies have shown cultural differences in attentional phenomena such as change blindness (Masuda & Nisbett, 2006), while learned visual experiences have been known to result in differential allocations of visual attention (Chun, 2000). In a similar vein, by demanding the allocation of attention to multiple objects, today's media-saturated environment may encourage the development of the capacity to split attention.

In our present study, we examine the suggested relationship between media usage and splitting attention. To this end, we borrow the Media Multitasking Index (MMI) developed by Ophir et al. (2009), a measure of simultaneous media usage. High and Low media multitaskers, as indicated by the MMI, have been found to demonstrate fundamental differences in cognitive control as well as information processing approaches. We believe that similar differences may be observed in the capacity to split attention as well. Furthermore, to strengthen the case that the contradiction between Lim and Lee (2010) and McCormick et al. (1998) stems from ecological, rather than paradigm, differences, we employed a close replication of McCormick's paradigm.

It is hypothesized that:

1. MMI should not result in between subject performance differences for the single cue conditions. All participants should demonstrate faster RTs for targets that appear in cued locations, over those that appear in irrelevant locations.
2. For the double cue condition, individuals who tend not to media multitask, as indicated by their Low MMI scores, should demonstrate unitary attention: RTs for targets at cued and irrelevant locations should be comparable;
3. However, individuals who tend to media multitask, as indicated by their High MMI scores should demonstrate split attention: RTs for targets at cued locations should be significantly faster than for those at irrelevant locations

## Method

This research was conducted in two parts: a media use questionnaire and matrix, followed by a cognitive behavioral experiment.

### Participants.

66 introductory psychology students participated for course credit.

### Media use questionnaire and matrix.

The questionnaire and matrix were close replications of those employed in Ophir et al. (2009), with one slight modification. Ophir and colleagues (2009) had included items about non-visual media forms, such as music, in their original study. Given that the present study is primarily interested in the deployment of visual attention, all such irrelevant items were removed. A decision was made to retain the 'Handphone' item, as technological advances have arguably transformed the handphone into a personal digital assistant used for many functions other than for phonecalls.

The questionnaire addressed 10 different media forms: printed media, television, computer-based video (e.g. YouTube), video or computer games, non-call related mobile phone usage, online instant messaging, text messaging, e-mail, web surfing, and other computer applications (e.g. Word processor). Participants were required to report the total number of hours spent per week on each media form. Furthermore, participants filled up a 9 x 10 media-multitasking matrix, indicating the degree to which, while engaged in one media form as a primary activity, they would concurrently use other forms of media as well (1 "Never", to 4 "Most of the time"). Text messaging was excluded as a primary media form in the matrix as its usage could not be accurately described as a function of time. However, it was still available as an option under concurrent activities.

### Deriving MMI

We recoded matrix responses as follows: 1 "Never" = 0, 2 = 0.33, 3 = 0.67, and 4 "Most of the time" = 1. Summing up responses for each primary media form gave a measure of the mean number of other media used concurrently for each primary activity. Finally, to account for the different amounts of time spent on each media form, MMI was derived by calculating a sum of this measure across all primary media forms, weighted by the percentage of time spent on each primary media form. This process can be summarized with the following formula:

$$MMI = \sum_{i=1}^9 \frac{m_i \times h_i}{h_{total}}$$

where  $m_i$  is the number of media typically used while using primary media form  $i$ ,  $h_i$  is the number of hours per week reportedly spent using primary media form  $i$ , and  $h_{total}$  is the

total number of hours per week spent with all primary media forms.

### Stimuli

As far as possible, the stimuli, design, and procedure of our experiment were kept in accordance with Experiment 1 of McCormick et al. (1998). While our participants completed fewer trials, the proportion of trials for each condition remained the same (see Table 1).

The visual display comprised of a black background and centered white fixation cross ( $0.4^\circ$  by  $0.4^\circ$ ). The cue used was an empty white-bordered square ( $1.1^\circ$  by  $1.1^\circ$ ) which appeared  $10^\circ$  to the immediate left of fixation,  $10^\circ$  to the immediate right of fixation, or in both locations simultaneously. The imperative stimulus was a white dot positioned at one of four possible locations on the horizontal median ( $10^\circ$  left,  $5^\circ$  left,  $5^\circ$  right, or  $10^\circ$  right).

### Design

The experiment used a  $3 \times 4$  fully within factorial design. The two independent variables were (1) type of cue: (a) single box to the left, (b) single box to the right, and (c) double box, and (2) location of target dot: (a)  $10^\circ$  left, (b)  $5^\circ$  left, (c)  $5^\circ$  right and (d)  $10^\circ$  right.

### Procedure

The sequence of events (see Figure 2 for schematic) for each trial was as follows: the fixation cross was presented for 800ms. This was followed by a single or double-box cue. After a 515ms interval, the target dot was presented and remained on screen along with the boxes until the participant responded. Participants were instructed to press the response key (spacebar) as soon as they detected the target, but to refrain from responding when the target did not appear (catch trials).

Participants were informed that the box cues indicated the most likely location at which the target would appear, and to orient their attention to these locations. Participants were also informed that in the event of a double box cue, the target could appear at either location with equal probability. Participants were further instructed to attempt to divide their attention between the two boxes when presented with a double box cue.

Each participant took part in a single experiment session consisting of 420 trials. Four rest periods were interspersed during this session. The total number of trials for each cue-target combination is presented in Table 1.

Table 1  
Number of trials for each Cue-Target combination.

Cue Type	Target Location				Catch
	$10^\circ$ left	$5^\circ$ left	$5^\circ$ right	$10^\circ$ right	
Double Cue	60	10	10	60	20
Single Cue, Right	10	10	10	80	20
Single Cue, Left	80	10	10	10	20

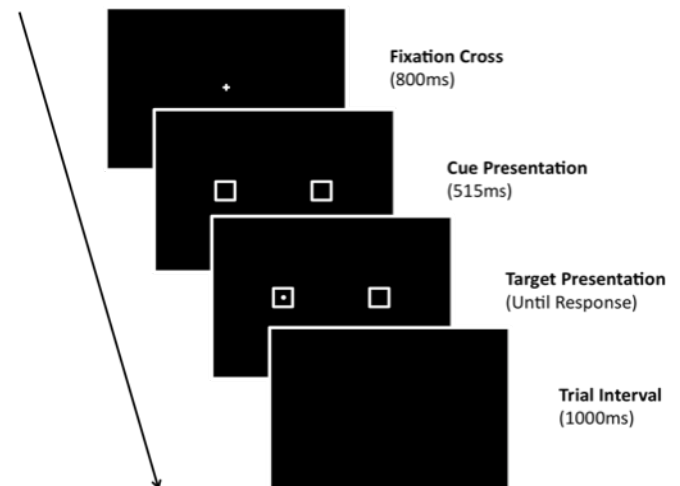

Figure 2. Schematic of the sequence of a trial.

### Results

Participant MMI scores ranged from 0.29 to 6.45, with an average of 3.15 and standard deviation of 1.37. There was no correlation between MMI score and the total number of hours spent on surveyed media forms each week,  $r(64) = .05$ ,  $p = .67$ . In preparation for further main analyses, participants with above-average MMI scores were classified as High scorers, whereas those with below-average MMI scores were considered Low scorers. Two groups of equal numbers were obtained: 33 High versus 33 Low scorers.

Responses on catch trials were only extremely rare (2.2% of catch trials), and no participants had to be excluded from analysis on this basis. For each participant, trials with RTs less than 150ms or in excess of 1000ms were regarded as errors and not analyzed (less than 1% of trials).

A repeated measures analysis of variance (ANOVA) was performed that included the variables cue type (left, right, or double) and target location ( $10^\circ$  left,  $5^\circ$  left,  $5^\circ$  right, or  $10^\circ$  right) as within-subject variables, and MMI (high or low) as a between-subject variable. Relevant means have been summarized in Table 2.

The Mauchly's test of sphericity was significant,  $p < .05$ , for the cue type  $\times$  target location interaction term, suggesting that sphericity was violated. Accordingly, a more stringent F-test (Greenhouse-Geisser) was used. Results revealed a significant main effect for cue type,  $F(2, 128) = 235.84$ ,  $p < .001$ ,  $\eta_p^2 = .90$ . There was also a significant main effect for target location,  $F(3, 192) = 34.44$ ,  $p < .001$ ,  $\eta_p^2 = .59$ . The main effect for MMI did not reach significance,  $F(1, 64) = 3.19$ ,  $p = .08$ . In terms of interactions, the cue type  $\times$  MMI interaction was non-significant,  $F(2, 128) = 0.99$ ,  $p = .37$ . Both the cue type  $\times$  target location and target location  $\times$  MMI interactions were significant,  $F(6, 384) = 189.49$ ,  $p < .001$ ,  $\eta_p^2 = .90$  and  $F(3, 192) = 4.66$ ,  $p < .01$ ,  $\eta_p^2 = .16$  respectively.

Most important, all effects were qualified by a significant cue type  $\times$  target location  $\times$  MMI interaction,  $F(6, 384) = 2.46$ ,  $p < .05$ ,  $\eta_p^2 = .21$ . Post-hoc tests revealed that the

Table 2  
Mean RTs (in ms)

MMI Score	Cue Type	Target Location			
		10° Left	5° Left	5° Right	10° Right
High	Left	307 (4.71)	358 (5.98)	358 (6.23)	380 (7.77)
	Right	397 (7.77)	380 (6.60)	361 (6.40)	304 (4.40)

	Right	372 (8.65)	355 (7.23)	348 (7.66)	297 (6.22)
	Double	306 (5.76)	306 (6.41)	310 (6.55)	307 (6.31)

Note: Standard errors are in parentheses.

target location x MMI interaction was non-significant for the left cue condition,  $F(3, 192) = 2.36, p = .084$ , but significant for the right and double cue conditions,  $F(3, 192) = 3.40, p < .05, \eta_p^2 = .05$  and  $F(3, 192) = 4.24, p = .01, \eta_p^2 = .22$  respectively. The significant target location x MMI interaction was examined individually for the right and double cue conditions. To test my hypothesis directly, we examined the simple main effect of target location at each level of MMI. For the right cue condition, the simple main effect of target location was significant for both High and Low MMI participants,  $F(3, 96) = 87.68, p < .001, \eta_p^2 = .90$  and  $F(3, 96) = 134.16, p < .001, \eta_p^2 = .81$  respectively. For the double cue condition, the simple main effect of target location was non-significant for Low MMI participants,  $F(3, 96) = 1.07, p = .36$ ; but significant for High MMI participants,  $F(3, 96) = 7.39, p < .001, \eta_p^2 = .19$ .

This 3-way interaction is reflected in Figure 3. A distinct RT gradient can be observed for both single cue conditions, regardless of the MMI scores of participants: RT was fastest at the cued location, and became slowed as the target was presented further from the cue. For the double cue condition, relatively constant RTs can be observed at each target location for Low MMI participants. For High MMI participants, a slight RT gradient can be observed between cued and irrelevant locations, with RTs being faster at cued locations.

As a further investigation of the 3-way interaction, and as a planned comparison, we collapsed both single cue conditions into one condition, and sorted the RT data by *trial type*. Specifically, we analysed the RT difference between *valid* trials, where the target appeared at cued locations, and *valid probe* trials, where the target appeared 5° to the left or right of cued locations. The outcomes are as follows:

For the single cue condition, the effect of trial type was significant regardless of the level of MMI. For both High and Low MMI participants: RTs on valid trials (Low: 300ms, High: 306ms) were significantly faster than those on valid probe trials (342ms, 359ms),  $t(32) = 11.05, p < .001$  and  $t(32) = 14.33, p < .001$  respectively (See Figure 4).

For the double cue condition, the effect of trial type was non-significant for Low MMI participants: RTs on valid and

valid probe trials were comparable (306ms vs 308ms),  $t(32) = 0.91, p = .37$ . In contrast, the effect of trial type was significant for High MMI participants: RTs on valid trials were faster than on valid probe trials (316ms vs 330ms),  $t(32) = 4.84, p < .001$  respectively (See Figure 5).

## Discussion

The present experiment has replicated one of the central findings in McCormick et al. (1998): Increasing RTs as targets are presented further from cued locations in the single cue conditions. This RT gradient has also been observed in prior studies which used probes to test the spatial extent of visual attention (e.g. LaBerge, 1983). Two interpretations have been offered to explain this gradient. Umiltà, Riggio, Dascola, and Rizzolatti (1991) proposed that increasing RTs could reflect the need to shift attentional focus, while McCormick and Klein (1990) suggested that the gradient could reflect diminishing concentrations of attentional resources at distances further from the cued location.

McCormick et al. (1998) did not observe such a gradient in their double cue condition. Accordingly, it was concluded that either participants had no need to shift attention to targets which appeared in irrelevant locations, or similar levels of attention had been deployed across all four potential target locations. Both interpretations are consistent with the idea of a single attentional focus expanded to encompass noncontiguous cued locations, as predicted by the zoom lens model.

Consistent with McCormick and colleagues' (1998) findings, no RT gradient was observed in the double cue condition for participants with Low MMI scores. RTs to targets appearing at cued and irrelevant locations were comparable. This suggests that a unitary mode of attention was being employed by these participants.

In contrast, the critical finding in the present experiment was the observation of an RT gradient in the double cue condition for participants with High MMI scores. RTs to targets at cued locations were faster than for those at irrelevant locations. As elaborated above, this suggests that: 1) High MMI participants had to shift attention from cued locations to attend to targets in the irrelevant region in between, or 2) High MMI participants had deployed higher concentrations of attention at cued locations, compared to irrelevant locations. Both interpretations are consistent with the idea of the deployment of two attentional foci in noncontiguous locations – a demonstration of split attention.

Taking these results together, an interpretation based on MMI variability seems to provide excellent insights into the conditions under which split attention tends to occur, which we elaborate below.

MMI is a measure of media multitasking behaviour. The 'score' obtained is an estimation of the number of media forms a participant tends to concurrently use in a typical hour of media consumption. Thus, the critical difference between Low and High MMI participants is the behavioural tendency to consume multiple visual media forms simultaneously. Our results have established the following:

1. People who tend to consume multiple visual media forms simultaneously, as indicated by High MMI scores, employed a split mode of attention when presented with cued noncontiguous locations.
2. People who tend to consume fewer visual media forms simultaneously, as indicated by Low MMI scores, employed a unitary mode of attention when presented with the same.

This suggests a relationship between simultaneous media usage and the capacity to split attention. If, as argued by Lim and Lee (2011), ecological differences in terms of the media-saturation of participants' environments account for the contradictory results between Lim and Lee (2011) and McCormick et al. (1998), this further suggests that the capacity to split attention ought to follow prolonged simultaneous media usage, and not vice versa (however, this remains an open empirical question at this juncture, as MMI scores could not be experimentally manipulated to provide a fuller claim).

How, then, might such a development take place? As suggested in Lim and Lee (2011), the employment of a split or unitary mode of attention could be a strategic decision made by the visual system, depending on whichever was the least effortful means of extracting information from a visual representation. It has also been suggested that maintaining a split mode of attention is inherently more effortful than unitary attention, and leads to performance costs (Cave et al., 2010). Pulling these trains of thought together, we

propose that prolonged simultaneous media usage acts as a form of practice which reduces the effort needed to maintain split attention. This, in turn, increases the occasions where split attention becomes strategically optimal, and thus employed in lieu of unitary attention. A new direction for future investigations would be to empirically test this hypothesis through the use of training studies.

With respect to existing split attention literature, the present study contributes to converging evidence which suggests that the deployment of multiple attentional foci is possible. Furthermore, the present study advances our understanding of the conditions under which focal attention might split. New evidence is presented, for the first time in the literature, supporting the possibility of individual differences in the capacity, or at least a tendency, to split attention. Potential individual differences, which need not necessarily stem from media multitasking behavior alone, might at least in part explain the body of conflicting results pointing to unitary attention. Prior attempts to reconcile conflicting findings have typically focused on paradigm differences (Dubois et al. 2009; Kramer & Hahn, 1995). A full picture may only be achieved by considering the interaction between individual and paradigm factors.

In addition, we wish to highlight that the present study contributes to the general finding that ecological experiences influence various visual attentional processes. An interesting direction of future research would be to explore the possibility of other ecological influences on the capacity to split attention. One possible candidate is habitual video game playing. Expert gamers are significantly better at identifying targets presented towards the periphery of their vision than non-gamers, which has been interpreted as superior ability at distributing attentional resources throughout the visual field (Green & Bavelier, 2003). Given that split attention can be conceptualized as the ability to deploy attention in a flexible manner, the attention distribution benefits stemming from habitual game playing might have an impact on the capacity to split attention as well. This possibility is both a theoretically as well as an empirically exciting one.

In conclusion, we report novel evidence that ecological differences, arising from our increasingly media-saturated environment and how we choose to interact with it, could lead to individual differences in the capacity to demonstrate split focal attention. This advances our understanding of the exact conditions under which focal attention might split, and might partly account for the conflicting evidence for and against split attention found in the literature. Further studies may consider other potential sources of individual differences in the capacity to split attention. Moving forward, we are very hopeful that ecological factors will continue to shed new light on the persistent puzzle of splitting visual focal attention.

## Abstract

We investigated the use of a caregiver's actions and eye-gaze in teaching whole or part names. The experimental material consisted of two everyday objects, a toothbrush (the whole name was "haburashi", the part name was "ke") and a ball-point pen. We coded 4 action type categories and 2 eye gaze type categories based on the video data of 19 4-year-old child-mother dyads using frame-by-frame method. Results of actions showed that when the caregiver uttered a whole object name such as toothbrush ("haburashi"), the caregiver tended to present the object to the child by showing it. When she uttered a part name to teach the part name such as brush ("ke"), she pointed at the object part. Results of eye gaze analysis showed whereas the caregiver tended to look at the child's face in teaching whole names, she tended to look at the object in teaching part names. We found that caregivers use different gestures and eye gaze directions to teach whole or object part names. The study suggests that caregivers help young children's word learning using appropriate gestures and gaze directions.

**Keywords:** gesture; showing; eye gaze; teaching part names.

## Introduction

It is claimed that children acquire language with the ability of specifying adults' referential intentions. This study focuses on adults' referential actions when they were asked to teach about whole objects or object parts to examine whether they provide useful information for young children's guessing adult referential intentions.

It is necessary for young children to accurately understand adults' intentional actions and associate accurately referred objects and words (Zukow, 1990). Adamson, Bakeman, and Deckner (2004) presented a study that a caregiver looked at a young child's eyes using mutual gaze when she taught an object name for the child. It is also important for young children to know an adults gaze direction (Doherty & Anderson, 1999). Doherty, Anderson, and Howieson (2009) showed 3-year-old children understood adults' subtle gaze direction.

Children are sensitive to the referential intentions conveyed by pointing and looking and they use information they obtained for word learning (Tomasello, Carpenter, & Lizkowski, 2007; Kobayashi, 1998, 1999). Tomasello & Farrar (1986) contended that mothers' object references that follow into children's attentional focus may facilitate their lexical acquisition. However an adult may not always offer information that is unambiguous and right. Baldwin (1991,

1993) investigated how children know adults' referential intentions using a discrepant labeling situation. In the discrepant labeling situation, an adult's attention at objects does not agree with a child's attention at objects. The study showed that 18 months or older children checked an adult's eye gaze to know the object which the adult labeled. In the everyday life, maternal naming and labeling for children often includes discrepant labeling situations (Collis, 1977; Harris, Jones, & Grant, 1983). Children must be equipped with ability to know correct referential intentions of adults using eye gaze and other information even in discrepant labeling situations.

Caregivers seem to use specific ways to convey referential intentions to young children. Masur (1997) examined caregivers' natural interaction with their infants using novel, comprehended, and familiar toy animals. The results were that mothers virtually always named whole objects first. More importantly, in the first mention of novel object, they named it and designated it with physical contact such as pointing, holding, or manipulating, but such naming and actions did not occur on the first mention of comprehended or familiar toy animals.

Although these studies provided precious evidence on adults' referential actions, these studies all focus on caregivers' teaching about whole object labels. An object is composed of various parts, so in part name learning, children should find a specific object part in a whole object and associate the part with the part name. It is not known whether caregivers use any specific referential actions or eye gaze to teach children part names.

In the literature of word learning, learning part names has been more discussed in the use of linguistic cues rather than nonlinguistic cues (Markman & Wachtel, 1988; Saylor, Baldwin, & Sabbagh, 2002). Markman and Wachtel (1988) showed that children learned part names when they could use knowledge about a whole object name and by applying whole object assumption and mutual exclusivity. Saylor, Baldwin, & Sabbagh (2002) demonstrated that if an object is presented and its whole-name and one of its part names are juxtaposed, children could learn the part name of the object. However, on whether children can learn part names using nonlinguistic cues, the results are mixed. Examined nonlinguistic cues were general direction of pointing (Mervis, Golinkoff, & Bertrand, 1994), facial expression (Moll, Koring, Carpenter, & Tomasello, 2006), tracing the contour of an object part (Hansen & Markman, 2009), and

functional actions (Kobayashi, 1998). Some cues have been demonstrated to help young children, but whether children use gestures such as pointing in learning part names is not well known.

Kobayashi (1998, 2002, 2012) showed that in the task to associate novel labels with object parts, 2- and 4-year-olds accurately interpreted adults' referential actions such as moving object parts or simply touch-pointing object parts to know word meanings. Yasuda and Kobayashi (2010) reported effects of eye gaze direction in learning part names. Children learned part names accurately when the adult pointed and looked at the object part and named the object part. However, if the adult looked at child's face doing the same actions, children DID NOT associate the object part with the part name. The study suggested that children learn part names accurately when adult focused on the object part by looking at the object part in addition to pointing at the object part. We speculated that caregivers may actually use referential actions and referential gaze so that young children understand whether the whole object or the object part is named.

In this study, we examined caregivers' referential actions in teaching part names to their 4-year-old children. We examined 4-year-olds' mothers because our previous research (Yasuda & Kobayashi, 2010) showed that 4-year-olds' mothers used referential actions such as pointing in teaching object part names. In addition, our recent research (2012) shows that 4-year-old children are sensitive to adults' pointing with touching the part. We decided to examine mothers' teaching gestures in two conditions, whole object name teaching and object part name teaching.

In Analysis 1, we asked a caregiver to teach either a whole object name or object part name and analyzed the caregiver's referential actions when she uttered either a whole label or a part label. In Analysis 2, we compared the caregiver's eye gaze when she uttered labels in each situation. If the caregiver used different referential actions when she uttered a whole and a part label, and if they use different eye gaze simultaneously with labeling whole or part labels, it can be said that they actually provide different nonlinguistic information for young children to help they learn whole and part labels.

## Method

Nineteen pair of 4-year-olds (Mean=56.25 SD= 3.455 Range= 52-63 months) and their caregivers participated in the experiment in the Greater Tokyo Area, Japan. This experiment was conducted in conformity with a privacy ethical code of Tokyo Denki University.

## Material

The experimental material consisted of toothbrush and ball-point pen as familiar objects. We prepared the toothbrush ("haburashi" in Japanese) as the whole object and a brush (Ke in Japanese) as the object part. We prepared a ball-point pen ("bohru-pen" in Japanese) as the whole object and a knock bottom ("nokka" in Japanese) as the object part.

These objects in each set had distinctive shapes, and had the same color and texture as the other parts of the material object.

## Procedure

The child and the caregiver sat at a table corner face-to-face (Figure 1). The experimenter recorded the experiment by two digital video cameras (Sony, SR-60, 29.97frame/sec). One of the video cameras focused on the caregiver's face and hand, and the child's face. The other video camera took the whole view to the experimental situation. These two video cameras were appropriately synchronized.

Each pair of participants was randomly assigned to one of two conditions, whole object teaching: the caregiver teaches something about the whole object (e.g. whole object name: toothbrush or "haburashi") and object part teaching: the caregiver teaches something about the object part (e.g. object part name: brush or "ke"). In the whole object teaching condition in the brush session, the experimenter gave the toothbrush to the caregiver and said to the caregiver in Japanese: "Please teach about the toothbrush as you like." ("Jiyu ni haburashi ni tsuite oshiete kudasai."). When the caregiver finished the brush session, she return the toothbrush and received the ball-point pen and taught about the ball-point pen. In the part teaching condition, the procedure was identical with the whole object teaching condition except that the caregiver was asked to teach the object part instead of the whole object. The experimenter asked the caregiver in Japanese: "Please teach about this brush part of this object." ("Jiyu ni kono ke no bubunn ni tsuite oshiete kudasai.").

Figure 1. The experimental setting

## Analysis 1

We examined whether the caregiver looked at the object or the child's face when the caregiver taught the whole object or the object part name. We categorized the caregiver's actions into four types (pointing, stroking, demonstration, and showing) based on video data (30 frame/sec) using frame-by-frame method. We coded the caregiver's actions when she uttered the first sound of either whole object name or object part name. We coded "pointing" when the caregiver pointed at the object. We coded "stroking" when the caregiver stroked the object contour. We coded "demonstration" when the caregiver demonstrated the function of the whole object or object part to present the child. We coded "showing" when the caregiver showed the object to the child. All caregivers' actions were categorized into one of these four categories. There were no caregivers who did not do any action when she uttered the first sound of whole object name or object part name.

We first calculated the frequency of each action type in each caregiver. Figure 2 shows the ratio of action type in each caregiver.

Figure 2. The ratio of action type in each caregiver.

## Results of Actions

In order to analyze each caregiver's most representative referential action, we also calculated the proportion of each caregiver's action type based on the caregiver's most frequently occurred referential action observed in each teaching condition.

To test whether caregivers' actions varied across teaching types, a 2 (Teaching: whole label naming and part label naming)  $\times$  2 (Action: pointing, stroking, demonstration, showing) chi-square test was conducted. There was a significant effect of teaching type,  $\chi^2(3)=9.6, p<.05$ .

To explore the significant effect, we conducted residual analysis by computing adjusted residual. When the caregiver pointed at the object, the caregiver uttered more part names ( $r=3.098, p<.05$ ) than whole names ( $r=-2.309, p<.05$ ). When the caregiver presented the object using showing, the caregiver uttered more whole names ( $r=2.498, p<.01$ ) than part names ( $r=-3.098, p<.01$ ).

These results indicate that 1) When the caregiver uttered the whole label, she tended to present the object by showing. 2) When the caregiver uttered the part label, she tended to point at the object.

The caregiver seemed to use appropriate gestures to convey her referential intention on the object. Caregivers pointed at the part when she uttered a part label. Here, she specified the object part and taught part names. The caregiver DID NOT point at the object when she uttered a whole name.

## Analysis 2

In Analysis 1, we examined whether a caregiver looked at the object or the child's face when caregiver uttered the whole object name or object part name. We categorized the caregiver's eye gaze into two types (object and child's face) based on video data (30 frame/sec) using frame-by-frame method. We categorized a gaze an object gaze if the caregiver looked at the object when she uttered an object name. We categorized a gaze a child's face gaze if the caregiver looked at the child's face or hand when she uttered an object name. We coded these gaze at the first sound of either whole or part names. No caregiver looked at the digital camera or others when she uttered whole or part labels.

We first calculated the frequency of each eye gaze type in each caregiver. Figure 3 shows the ratio of action type in each caregiver.

Figure 3. The ratio of gaze type in each caregiver

## Results of Eye-Gaze

In order to analyze each caregiver's most representative eye gaze, we also calculated the proportion of each caregiver's eye gaze type based on the caregiver's most frequently occurred referential gaze observed in each teaching condition.

To test whether caregivers' eye gaze varied across teaching types, a 2 (Teaching: whole label naming and part label naming)  $\times$  2 (Gaze: Object, Child's face) chi-square test was conducted. There was a significant effect of teaching type,  $\chi^2(1)=12.40, p<.01$ .

To explore the significant effect, we conducted residual analysis by computing adjusted residual. When the caregiver looked at the object, the caregiver uttered more part names ( $r = 3.528$ ,  $p < .01$ ) than whole names ( $r = -3.528$ ,  $p < .01$ ). When the caregiver looked at the child's face, the caregiver uttered more whole names ( $r = 3.528$ ,  $p < .01$ ) than part names ( $r = -3.528$ ,  $p < .01$ ).

These results indicate that 1) When the caregiver taught the whole label, she looked at the child's face or hand. 2) When the caregiver taught the part label, she looked at the object. The caregiver looked at the object when she presented the object with a showing gesture. She rarely looked at the object when she taught the whole name with a showing gesture

## Discussion

We investigated the relationship between a caregiver's actions and eye gaze in teaching whole or part object names. The experimental material consisted of two everyday objects, toothbrush (whole name is "haburashi", part name is "ke") and ball-point pen (whole name is "boru pen", part name is "knocker"). We coded 4 action type categories and 2 eye gaze type categories based on the video data using frame-by-frame method.

Results of action data showed that the caregiver presented the object by showing it when she uttered a whole object name such as toothbrush. However, the caregiver pointed at the object when she uttered a part name to teach the part name such as brush. Thus the caregiver taught part names using pointing at the object part. Caregivers may know their children can learn part names by observing adult pointing actions. Pointing at object part can appropriately attract the child's attention to the object part. That may be one reason why caregivers choose to use showing rather than pointing in whole object naming so that the child can appropriately focus on the whole object rather than any specific part of the object.

Results of eye gaze data showed that whereas caregivers tend to look at a child's face in teaching whole names, they tend to look at an object itself in teaching part names. Caregivers seem to know looking at the object part in addition to pointing the object part is important to teach children object part names.

It is suggested that the caregiver conveys referential intentions to teach whole or object part names using appropriate gestures and gaze direction. The results of this study accord with social-pragmatic approach to word learning (Clark, 2009; Tomasello, 2003). Children learn word meanings by guessing adult intentions provided by adult utterances. This study provided evidence that adult certainly provide nonlinguistic information through gestures and eye gaze to help children's understanding of adult referential intentions.

## Abstract

This study investigated the use of state-trace analysis (Bamber, 1979) when applied to computational models of human learning. We aimed to investigate the performance of simple recurrent networks (SRNs) on a sequence learning task. Elman's (1990) SRN and Cleeremans & McClelland's (1991) Augmented SRN are both benchmark models of human sequence learning. The differences between these models, comprising of an additional learning parameter and the use of response units activated by output units constituted our main manipulation. The results are presented as a state-trace analysis, which demonstrates that the addition of an additional type of weight component, and response units to a SRN produces multi-dimensional state-trace plots. However, varying the learning rate parameter of the SRN also produced two functions on a state-trace plot, suggesting that state-trace analysis may be sensitive to variation within a single process.

**Keywords:** Learning; state-trace analysis; SRN; sequence learning; Augmented SRN;

## Introduction

State-trace analysis (Bamber, 1979) is a method that aims to establish whether one or more underlying processes are influencing behavior on a given task. The method has been applied to a variety of paradigms, including remember-know tasks (e.g. Dunn, 2008), face recognition (e.g. Loftus, Oberg, & Dillon 2004), categorization (e.g. Newell, Dunn & Kalish, 2010) and a variety of other areas (see Prince, Brown & Heathcote, 2011).

The procedure for a state-trace analysis is to plot the relationship between two dependent variables (*dimensions*) on two or more tasks (*states*). If these points follow a single, monotonic function, it can be hypothesized that the same latent variable underlies performance on the tasks. The influence of more than one latent variable on the tasks is implied when the state plots do not follow the same function, i.e. more than one monotonic function is visualized.

Computational models are created in the full knowledge of the processes involved in their construction. Thus, the primary use of state-trace analysis, to attempt to quantify latent psychological variables, does not seem to directly lend itself to computational modeling. But the fact that we should be able to make some predictions from the nature of the models about the types of processes involved in any simulation helps us interpret any state-trace analysis of the data produced by the simulation. This paper seeks to apply state-trace analysis to the simulation results produced by computational models on a sequence learning task both to

evaluate the different types of model and as a means of evaluating the state-trace methodology itself.

The computational models chosen for this analysis are the simple recurrent network (SRN) introduced by Elman (1990) and the Augmented SRN (Cleeremans and McClelland, 1991). The basic SRN model is simple (see Figure 1), involving feed-forward input activation through a hidden layer. The activations of this hidden layer are copied back on each trial into a context layer, which is then fed back into the hidden layer as input on the next trial. This ensures that the representations of the previous trial are carried over, and gives the model the ability to learn sequential information.

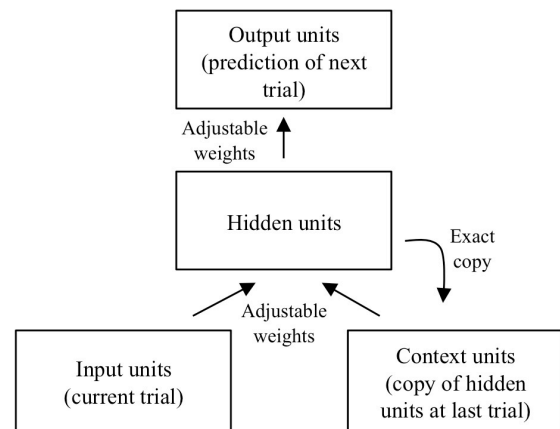

Figure 1: The architecture of the SRN (Elman, 1990).

Cleeremans and McClelland (1991) further developed the SRN in order to give a better account of the sequential effects demonstrated by human participants. This augmented simple recurrent network (AugSRN) differs from Elman's (1990) original architecture firstly in the inclusion of response units post-output. As a consequence, when making a response to the stimuli in an experiment, this response remains primed over future trials for a short time (Remington, 1969), because the response units are activated by the output units and feed activation back into the output units on the next trial.

The AugSRN also accounts for the priming of certain sequential pairings (Cleeremans & McClelland, 1991) by assuming that back propagation is implemented on not one set of connection weights, but two. One component is a set of slow weights, which produce small but permanent changes with minimal decay. These are complemented by fast weights, which have a higher learning rate but also a

greater rate of decay: simulating transient, short-term learning.

Both models have successfully simulated a range of human datasets (Cleeremans, 1993), including modeling sequence learning in serial reaction time (SRT) tasks. Jones and McLaren (2009) found that an AugSRN could produce the detailed pattern of subsequence learning demonstrated by participants in their experiments. Using a two-choice SRT task participants received continuous strings of stimuli that followed an exclusive-or rule two-thirds of the time. If the previous two responses were the same (XX or YY), then the current trial would be one response (X), and if the previous two had not been the same (XY or YX) this would lead to the other response (Y). Participants under incidental conditions found it hard to learn about the subsequence XXX compared to the other types, a result which was successfully simulated by the AugSRN.

In a later experiment Yeates, Jones, Wills, McLaren and McLaren (submitted) used the same two-choice SRT task to investigate human sequence learning. Participants in this study were divided into two groups, both of which received sequences governed by a rule that they were not informed about. In one group, the current trial could be predicted two-thirds of the time to be different to the trial before last, i.e. 'first different to third' (Group 1: XXY, XYY, YYX, YXX) and in the other the current trial would be predicted to be the same as the trial before last, 'first same as third' (Group 2: XXX, XYX, YYY, YXY). Poorer performance was predicted in Group 2 under incidental conditions based on Jones and McLaren's (2009) earlier findings that participants were unable to learn about subsequence XXX (or YYY). The manipulation did indeed produce this difference between Groups. We found that variants of the SRN and AugSRN could simulate these data to differing extents depending on the parameterisation of the model (Yeates et al., submitted), which suggests that the differences between the SRN and AugSRN may be of interest in this context.

SRNs are considered to be single-process models (e.g. Frensch & Miner, 1994; Kinder & Shanks, 2003), where parameters can be altered to produce different effects, but these involve essentially one process. The standard view is that the two connection weight components in an AugSRN represent the same kind of process; of learning through back propagation, and that their differences are of amount and not kind. Varying the learning rate affects the efficiency of learning across training (Kinder & Shanks, 2001; McClelland & Rumelhart, 1986). However, one might hold the view that the two connection weight components are in fact different processes within the AugSRN, accounting for long- and short-term learning. Similarly, as response units were introduced to take account for short term priming of the previous response (Cleeremans & McClelland, 1991), we could argue that this additional component may also represent an additional, different process.

We therefore hypothesize that when comparing performance of the SRN and AugSRN we will see a clearly

multi-dimensional state-trace plot, as the two models are different in kind. Further to this, we aim to examine the components of the AugSRN in more detail, with the aim to investigate whether state-trace analysis considers these additions to the original SRN separate processes within the model.

Given this analysis, our approach was to produce a state-trace analysis of these models' performance on a task based closely on the two-choice serial reaction time (SRT) experiments described in Jones & McLaren (2009) and Yeates, Jones, Wills, McLaren and McLaren (submitted). We aimed to compare the performance of these networks on this task, varying the free parameters of the models.

## Modeling Sequence Learning

The SRT paradigm involves participants responding to stimuli on screen that follow some sequence (Nissen & Bullemer, 1987; Lewicki, Czyzewska, and Hoffman, 1987). Therefore, faster and more accurate responses are expected for those trials that are predicted by the sequences learnt in comparison to a control group, who would receive the same task but with a pseudorandom ordering (e.g. Anastasopoulou & Harvey, 1999, Jones & McLaren, 2009).

## SRT Task Outline

The task experienced by each network follows closely that we have used with human participants, and lasted for two sessions, each with 20 blocks. Each block comprised 120 continuous trials of stimuli appearing on the right or left. The sequences making up each block were constructed differently for Group 1 and 2, and for the networks acting as control groups. For the experimental networks, all blocks in the first session and the first fifteen sequences in the second session were constructed from 40 triplets that followed the rule for each Group (Group 1: XXY, XYY, YYX, YXX; Group 2: XXX, XYX, YYY, YXY). Networks thus received ten of each subsequence type per block.

Two-thirds of experimental training trials followed the rule, as the third trial in a triplet was always consistent with the rule, as were half of first and second trials in a triplet by chance when subsequences were randomly concatenated. Test and control group training blocks were made up of pseudorandom sequences that included an equal amount of all subsequence types.

## Model Construction

The parameters varied in the model for the purpose of the state-trace analysis are the number of hidden units and the learning rates, as well as the presence or absence of response units and presence of one or two connection weight components. Two units for both input and output were chosen to represent the stimuli (right or left circle fill) and predictions for the next trial (right or left), respectively. The activation of a single input unit was set to one, with the other set to zero to correspond to a left or right stimulus presentation. The units in each layer, from input and context to hidden and to output units, fed activation forward to

every unit in the layer above (see Figure 1). The activation of the hidden and output units were determined by the logistic activation function (Rumelhart, Hinton, & Williams, 1986). Hidden unit activation was copied back to the context units on each trial with a lag of one cycle of the network. Each hidden unit also had a bias: a variable connection from a unit that had a constant activation of one. The hidden units mapped recurrently to the context units on a one-to-one basis. The feed-forward connections comprised of either one or two connection weights. These were modified by the back-propagation algorithm, which we ran without a momentum term (Rumelhart et al., 1986).

To simulate the experiment with humans reported in Yeates et al. (submitted), each model was run 128 times to match the number of participants taking part in the empirical study. Half of these simulations acted as controls (trained on pseudorandom sequences), with half receiving experimental sequences. 32 experimental networks followed Group 1 rules ('first different to third') and 32 followed Group 2 rules ('first same as third'). Initial connection weights were set for each network to random values between -0.5 and 0.5. Each simulation involved training for one session and fifteen blocks of a second session, followed by five blocks of test sequences. Therefore each simulation received 4200 training trials and 600 test trials.

The mean square error (MSE) was calculated as the difference between the location of the next trial, and the prediction of the model (see Jones & McLaren, 2009). This was taken as the measure of performance of the model on the task. As in previous simulations of these tasks, the MSE for trials consistent with the trained rule was taken from the MSE for inconsistent trials (Jones & McLaren, 2009; Yeates et al., submitted). This produces an estimate of learning about those trained sequences, and is also computed for control simulations. Half of the control simulations are assigned to the dummy variable Group 1, where 'first different to third' subsequences (XXY, XYY, YYX, YXX) are taken from the matching 'first same as third' subsequence (XXX, XYX, YYY, YXY). The remaining 32 simulations follow the Group 2 inconsistent-consistent calculation, with the MSE on 'first same as third' subsequences taken from the MSE on 'first different to third' subsequences. Comparing the differences between experimental and control groups on these scores allows learning to be assessed without any confound in terms of sequential effects (see Anastasopoulou & Harvey, 1999; Jones & McLaren, 2009). To summarize then, good learning will result in a larger difference of the form (Control network MSE for inconsistent trials - Control network MSE for consistent trials) - (Experimental network MSE for inconsistent trials - Experimental network MSE for consistent trials), as a lower MSE indicates better learning.

### State-Trace Analysis 1: SRN and AugSRN

The task was simulated on an SRN and AugSRN with 20 hidden units. The SRN had a learning rate of 0.4, the AugSRN had a slow learning rate of 0.4 and a fast learning

rate of 0.533. The AugSRN also possessed response units, unlike the SRN.

**Results.** Both models produced significant learning of both sequences, which was analyzed by means of an ANOVA with subsequences and blocks as within-subject factors, and experimental versus control as a between subject factor. The SRN exhibited a significant difference in consistent-inconsistent MSE scores between experimental and control simulations,  $F(1,124) = 613.6, p < .001$ . The AugSRN also demonstrated learning,  $F(1,124) = 1113, p < .001$ . As this difference of differences measures the learning in experimental networks compared to networks that experienced pseudorandom sequences (controlling for sequential effects), this difference is used to provide our index of learning and performance in what follows.

The SRN and AugSRN constituted the two states we wished to analyze, and we plotted performance of Group 1 against Group 2 on the axes as the dimensions. The plots follow the trace of training over collapsed blocks of five, with the seven points shown constituting the 35 training blocks. Figure 2 shows the state-trace plot of this data.

Figure 2. State-trace plot showing learning of AugSRN and SRN across training blocks of simulations.

Inspection of Figure 2 clearly suggests that there are two different, monotonic functions on the plot. We analyzed the data using hierarchical multiple regression, with the hypotheses that the model predicting Group 2 performance from Group 1 performance would be improved by the addition of Model Type as a variable, indicating a multi-dimensional model of the data. We simply coded this as a dichotomous nominal variable, with the AugSRN arbitrarily labeled as 1 and the SRN as 2. The addition of Model Type into the regression model significantly improved the  $R^2_{adj}$  value from 70.2% to 92.1%,  $\Delta R^2: F(1,11) = 34.1, p < .001$ , and overall, the model had a significant fit,  $F(2,11) = 76.7, p < .001$ ;  $\text{Group 2} = -.944 \times \text{Group 1} - .029 \times \text{Model Type} + .064$ . This corroborates the impression that the data on this plot require more than one function for a good fit, which

suggests that there is more than one underlying process governing performance in these simulations. The conclusion is that the SRN and the AugSRN differ in kind (which is perhaps not surprising – though they are very similar types of model), but the important finding here is that the state-trace methodology is sensitive to this difference.

**Discussion.** This confirms our predictions about how we expected state-trace to represent learning by these different networks on this task, producing different functions and so confirming that they are genuinely different types of model. This could easily be attributed to either or both of the two differences between the SRN and AugSRN. We now investigate whether these models are themselves best characterized as single or multi-process models of learning.

## State-Trace Analysis 2: Connection weight components

Here we ran simulations on four different models, two had response units and two had no response units. Within these dyads, we aimed to compare whether fast and slow weight components (the states in this state-trace analysis) were driving the multi-dimensional model seen in our first State-Trace Analysis. Therefore Model 1 had one connection weight component with response units, Model 2 had two connection weight components with response units (an AugSRN), Model 3 had one connection weight component with no response units (a standard SRN), and Model 4 had two connection weight components with no response units. Both had 20 hidden units and slow and fast weights of .4 and .533 respectively, as in the previous simulation.

**Results.** All four models learnt the sequences, analyzed as in Simulation 1. Model 1 showed a significant difference between experimental and control performance,  $F(1,124) = 853.6, p < .001$ . Models 2 and 3 showed learning, as seen in the results of State-Trace Analysis 1. Finally, Model 4 demonstrated the same learning,  $F(1,124) = 1634, p < .001$ .

When comparing models with one and two connection weight components we can see from Figures 3 and 4, which show the state-trace plots for models with and without response units respectively, that two monotonic functions appear.

When conducting a hierarchical linear regression as described in State-Trace Analysis 1, we this time coded Model as a predictor with the values of 1 and 2 for one and two components, respectively. Introducing Model into the regression alongside Group 1 in predicting Group 2 performance for models with response units (see Figure 3) produced a significant improvement in the  $R^2_{adj}$  value from 84.7% to 93.1%,  $\Delta R^2: F(1,11) = 15.9, p = .002$ , and overall, the model had a significant fit,  $F(2,11) = 89.4, p < .001$ ;  $\text{Group 2} = 1.231 \text{ Group 1} + .014 \text{ Model Type} - .007$ . Similarly, when there are no response units (see Figure 4) adding Model as a predictor improves the regression model, with a significant improvement in the  $R^2_{adj}$  value from 56.0% to 89.6%,  $\Delta R^2: F(1,11) = 40.0, p < .001$ , and overall, the model had a significant fit,  $F(2,11) = 56.9, p < .001$ ;  $\text{Group 2} = 1.008 \times \text{Group 1} + .042 \times \text{Model Type} - .041$ .

Figure 3. State-trace plot for Model 1 (one connection weight component) and Model 2 (two connection weight components) across training.

Figure 4. State-trace plot showing learning of Model 3 (one connection weight component) and Model 4 (two connection weight components), neither of which have response units, across training.

**Discussion.** Both in models with and without response units, multi-dimensional state-trace plots are produced when comparing those with one or two connection weight components. The state-trace analysis suggests that the two models are driven by different underlying processes, which in this case is due to the presence or absence of fast weights. Following the state-trace logic, this suggests that the two weight components within an AugSRN should be considered as distinct, different learning processes.

### State-Trace Analysis 3: Response units

Does the addition of response units to the basic SRN, or an SRN with two connection weight components, produce separate functions on the state-trace plot? The same four models are presented below, comparing Models 1 (no response units) and 3 (with response units), which both have one component, and Models 2 (no response units) and 4 (with response units), which both have two connection weight components.

**Results.** We compare Models depending on whether they have response units or not, coded as 1 and 0, respectively. See Figures 5 and 6 for state-trace plots of one and two connection weight component models. We find that in models with one component, adding Model as a variable improves the regression model, the  $R^2_{adj}$  value improves from 92.3% to 95.6%,  $\Delta R^2: F(1,11) = 10.3, p = .008$ , and overall, the model had a significant fit,  $F(2,11) = 143.8, p < .001$ ;  $\text{Group 2} = .942 \times \text{Group 1} + .013 \times \text{Model Type} + .006$ .

Figure 5. State-trace plot showing learning of Model 1 (with response units) and Model 3 (no response units), which both have only one connection weight component, across training blocks of simulations.

Comparing Models 2 and 4, with response units, the regression does not significantly improve when adding Model as a variable into the regression.

**Discussion.** Whilst the functions are not as distinct as in State-Trace Analysis 2, the comparison of models with and without response units still suggests a multi-dimensional structure. That the models with two connection weight components failed to reach significance is perhaps more a criticism of the linear regression method when analyzing these data. The fact that the separation of the two plots is less impressive (in size and reliability) when the presence (or not) of the response units is the manipulation than when the use of one vs. two sets of weights also suggests that for the type of model considered here, the main difference

between the AugSRN and the standard SRN is the distinction between fast and slow weights.

Figure 6. State-trace plot showing learning of Model 2 (with response units) and Model 4 (no response units), which both have two connection weight components, across training blocks of simulations.

### State-Trace Analysis 4: Learning Rates

Finally, to ensure that the differences seen in State-Trace Analysis 2 between one and two component models were not simply a result of the total amount or rate of learning, we varied the learning rates of the one component model, keeping the hidden units set at 20. We set the learning rate to 0.933, equal to the sum of the fast and slow learning rates employed in the AugSRN simulations to plot alongside the earlier one process model with a learning rate of 0.4. We are aware that a one component SRN with a learning-rate equal to the sum of two component's learning-rates is not a direct equivalent. Nevertheless, our manipulation should allow us to discover if varying learning rate over this range produces different state-trace plots.

**Results.** An SRN with a Learning Rate of 0.933 learns the task,  $F(1,124) = 556.8, p < .001$ . The state-trace plot of these data, alongside the original Learning Rate of 0.4 can be seen in Figure 7, which clearly shows two functions. When adding the learning rate as a regressor into a model predicting Group 2 performance from Group 1 performance, the  $R^2_{adj}$  value improves from 75.8% to 92.4%,  $\Delta R^2: F(1,11) = 27.2, p < .001$ , and this model overall had a significant fit,  $F(2,11) = 79.9, p < .001$ ;  $\text{Group 2} = .895 \times \text{Group 1} + .048 \times \text{Learn Rate} - .010$ .

**Discussion.** The state-trace plot and the regression analysis clearly demonstrate two separate functions, which according to state-trace analysis suggests the presence of multiple processes. However, the two models differ only in the values assigned to their learning rates. State-trace analysis proposes that a multi-dimensional state-trace plot will result from the presence of multiple processes in a given dataset,

which implies the influence of more than one latent variable within the SRN on performance. This suggests that either state-trace analysis is sensitive to differences within a single process, or alternatively the SRN must be considered a multi-process model of learning.

Figure 7 State-trace plot for an SRN with different learning rates (shown on graph).

## General Discussion

The analyses of SRNs with one or two learning components, and those with or without response units give separate functions on state-trace plots, suggesting the presence of more than one latent psychological variable. However, simple variation of the rate at which the SRN learnt also produced a multi-dimensional state-trace plot, which raises questions for the interpretation of multi-dimensional state-trace plots. A parameter search, varying learning rates and number of hidden units, has been conducted and, within a reasonable range for the SRN on this SRT task, produces the same functions as the data presented above. We recognise that the regression method employed in analysing the data is limited to roughly linear functions, and suggest that other methods (e.g. Newell, Dunn & Kalish, 2010; Prince, Brown & Heathcote, 2011) are also explored. But our analyses are, if anything, insensitive to the differences visualised by the plots, so this does not compromise our conclusions.

It seems, then, that not only multiple processes, but variations within a single process can produce multi-dimensional state-trace plots. The implications for state-trace analysis as a tool for the investigation of the number of latent variables underlying human behaviour needs to be considered, and further analysis of computational models with this technique is recommended.

## Abstract

The current study examines the role of attention in forming complex binding structures in episodic memory. Previous research (Yim, Dennis, & Sloutsky, 2011a, 2011b) indicated that three-way bindings can be formed within an explicit memory task. Here we attempt to reduce explicit attending by presenting participants with a variant of statistical learning. The paradigm was modified to accommodate the constraints in two list learning paradigms ABABr, and ABCD. Only the ABABr paradigm requires a three-way binding in order to perform above chance. Evidence of learning was derived from learning curves, accuracies and reaction time at test. Results show evidence of learning for the ABCD condition but not for the ABABr condition. This finding indicates that whereas the ABCD structure can be learned implicitly, learning of ABABr lists depends on attention and requires explicit learning.

**Keywords:** episodic memory, attention, three-way binding, context use, statistical learning

## Introduction

One of the memory tasks that we confront daily is finding where we parked our car at work. Even though the only thing that one needs to remember seems to be the parking spot, one's car, and the link between the two, we often fail. One of the reasons that we are sometimes unable to retrieve this memory is because our previous memories of parking the car interfere with today's memory. Therefore in order to correctly retrieve today's event, we also need to remember the link between the context (i.e. today) and the event (i.e. parking the car in a specific spot).

As depicted in the above example, one's success in retrieving an episode depends on what was remembered, and how it was structured when it was remembered. Depending on the episode that one has to remember, there could be differences in the number of components that have to be remembered, and the structure that has to be formed. The process by which one forms a memory representation

containing multiple components is called *binding* (Cohen & Eichenbaum, 1993; Schacter & Tulving, 1994). Along with the ability to store the bounded memory components, it has been argued that control processes such as memory strategies and metacognitive operations also play a central role in forming episodic memory (Ghetti & Lee, 2011). However, how binding occurs and the nature of the structure it forms are still not clear.

Yim, Dennis, & Sloutsky (2011a, 2011b) proposed that a key determinant of performance during episodic memory formation is simultaneously attending to the components that should be remembered (e.g. events, context). This attentional mechanism was argued to be used during encoding and/or retrieval especially when the binding structure is complex. To support the argument, they presented a list learning paradigm to different age groups (i.e. 4-year olds, 7-year olds, and adults). The participants had to remember two lists each consisting of six pairs of pictures. The two lists were separated by a retention interval and the pairs were presented one at a time. At the end of studying the two lists a cued recall test was given with a context cue and an item cue (see Figure 1-(a) left slide for an example of a trial which has a context cue and two items). The main manipulation was the structure of the lists which varied the complexity of their required binding structure.

In an ABABr condition two lists had an identical picture set with the only difference between the two lists being how they were paired (Porter & Duncan, 1953; Postman, 1964, see Figure 1-(b) left). For example, in the first list there would be two pairs, [apple]-[dog] and [chair]-[car], and in the second list there would be two different pairs, [apple]-[car] and [chair]-[dog], which is a re-arrangement of the first two pairs. It has been logically illustrated by Humphreys, Bain, & Pike (1989) that to correctly answer a given cued recall test (e.g. what was paired with apple in list1?) one must have formed, at the minimum, a *three-way binding* structure that includes the two items [apple] and

[dog], and the context [list1] together. Suppose that one formed a simpler binding structure such as a two-way binding structure (e.g. [apple] – [dog] or [apple] – [car]). In this case when cued with “apple” and “list1” in a cued recall test (e.g. what was paired with apple in list1?), the [apple] will not only elicit [dog] in list1 but also [car] in list2, which would make one’s recall ambiguous. However, if one formed a three-way binding structure, [apple] and [list1] will act as a compound cue, and will elicit the correct answer [dog].

In an ABAC condition (see Figure 1-(b) middle), the cues were identical between the two lists whereas the targets were different. In this condition the minimal binding structure that is required to remember the episode correctly are known to be *two two-way binding* structures (Barnes & Underwood, 1959; Postman, 1962). For example, one should have formed at least the binding between the two items (e.g. [apple] – [dog]) and the binding between an item and the context ([list1] – [dog]) to correctly answer at test (e.g. what was paired with apple in list1?). If one had only formed a single two-way binding structure in this case, it would be hard to recall the correct answer since [apple] has multiple two-way bindings, which are [dog] and [rat]. However, if one had formed two two-way binding structures, the item to context binding (e.g. [list1] – [dog]) would restrict the multiple bindings and lead to a correct response, [dog].

Finally, in an ABCD condition two lists contained different items (see Figure 1-(b) right). Therefore a single two-way binding structure between the two items would be sufficient at test without considering the context (provided the items are selected so that there are no preexisting bindings between them).

A multinomial process tree (MPT) model (see Batchelder & Riefer, 1999 for a review) was used to quantify the relative contributions of the cue-target, context-target and the three-way binding structures. Differences among age groups were mainly restricted to the three-way binding structure. In particular, the improved ability to form three-way bindings differentiated the 7 year olds and adults, suggesting that development of the critical mechanisms is extended, perhaps through the teenage years. In a follow up study, Yim and colleagues increased the saliency of the context cue for 4 year olds (e.g. visiting Elmo’s house instead of visiting a green house, see Figure 1-(a) right slide). By increasing the saliency of the context cue, 4 year olds increased the ability to use the context information (list). If the formation of episodic memory (or three-way binding structure) only relied on having the representational capacity to bind memory components, the manipulation of stimulus attention (or saliency) should not affect one’s performance. However, the results suggest that simultaneous attention to components is required for successful binding. It was also argued that since children have low attentional control (Zelazo, Carlson, & Kesek, 2008), the developmental mechanism underlying episodic

binding would be relying on attentional control during encoding and/or retrieval.

From the above results, it seems that attention plays an important role in binding, especially for the three-way binding structure. The goal of this research is to test this hypothesis directly. To ensure low or no attention, a statistical learning paradigm (Saffran, Aslin, & Newport, 1996) was used by modifying the task used in Yim, Dennis & Sloutsky (2011). In the modified task, participants saw a sequence of cartoon characters one at a time and their task was to distinguish whether the character was a male or a female while their accuracy and reaction time were measured. The sequence had a specific pattern resembling the ABCD condition and the ABABr condition that were used in the previous study. However, instead of presenting the two items and context together, the items and context were presented sequentially using pictures of cartoon characters (see Figure 1-(c)). Therefore, there was always a picture representing the list context followed by two pictures which represented the items. The main prediction was that if two items and context are bound together during learning, the triplet would be segmented as in the original statistical learning paradigm. Therefore, it would be possible to predict the third picture after seeing the first two pictures in the triplet (Turk-Browne, Simon, & Sederberg, in press). As a result, faster reaction time or higher accuracy at the third item in a triplet would be an indicator of learning the triplet.

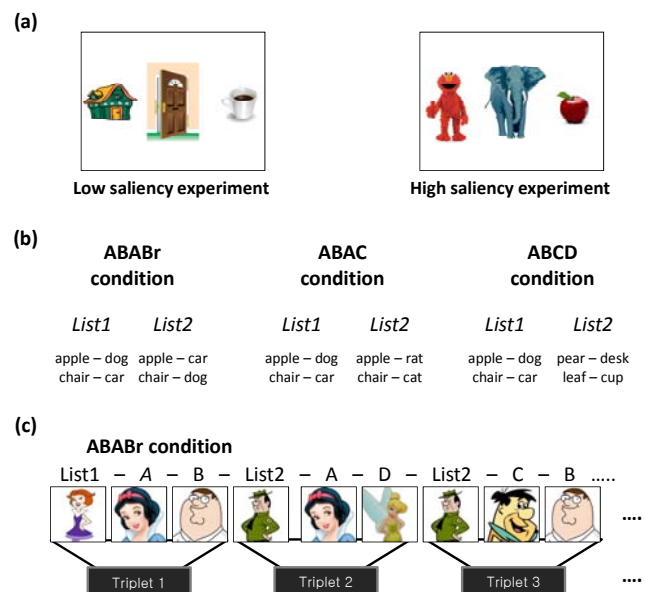

Figure 1: An illustration of experiment used in Yim, Dennis, & Sloutsky (2011a, 2011b) and its modification. (a) Stimuli used in the original experiment. The ‘green house’ and ‘Elmo’ represents the context cue whereas the ‘door’/‘apple’ represents the item cue, and the ‘cup’/‘elephant’ represents the target items (b) An example of the structure of the list in three conditions. (c) A modification of the original list learning paradigm (ABABr condition) into a statistical learning paradigm.

## Experiment

### Method

**Participants** Eighty undergraduate students at The Ohio State University participated for course credit (44 females,  $M = 19.11$  years,  $SD = 1.38$  years). Ten additional participants were excluded from the sample due to pressing the wrong key ( $N=5$ ), chance level accuracy ( $N=4$ ), and not understanding the instructions ( $N=1$ ).

**Stimuli** The stimuli were thirty six pictures of cartoon characters where half were male and the other half female. Post-experimental questions indicated that the sex of each character was easily determined by the participants. Each picture was presented on a white squared patch (10.55cm  $\times$  10.55 cm), which was centered on a black background of a 17inch computer monitor. For every participant, the pictures were randomly assigned to each experimental condition following the constraint of each condition.

The practice phase preceded the experiment and had five male and five female pictures where the order of presentation was randomized. The pictures in the practice were not used in the experiment. All experimental conditions including the baseline condition consist of triplets (i.e. context and two items). In each experimental condition, there were four unique triplets in the learning phase and an additional four unique triplets at test (see Figure 2-(a), (b)). The triplets in the learning phase followed the structure of the two list learning paradigms (i.e. ABABr, and ABCD) but were presented one at a time following the order of [context]-[item1]-[item2]. At test, participants were presented with triplets consisting of the learned elements, such that some of the triplets conformed to the learned statistics (i.e., Congruent) and some did not (Incongruent). Since the current paradigm examines the existence of a binding structure via the predictability of the third item based on the first two items, it is important to manipulate the third item at test while controlling the first two items. For example, in the ABABr condition if the first triplet (X1-A-B) was learned, which would mean that a three-way binding structure among the context (X1) and the two items (A and B) is formed, after seeing a sequence of X1 and A, it would be able to predict that the next item would be B. Therefore, response time or/and accuracy of item B would be faster or higher. On the other hand, a corresponding incongruent triplet (i.e. X1-A-D) would results in a slower response time or lower accuracy since the sequence violates the learned statistics and would interfere with the learned prediction “B”.

In each learning phase, there were ten repetitions for each unique triplet. In a repetition there were four unique triplets which result in a total of 120 (10 (repetition)  $\times$  4 (number of triplets)  $\times$  3 (pictures in a triplet)) trial per learning phase. In addition to the learning phase, the test phase consisted of 8 triplets, which had 4 congruent triplets identical to the learning phase and 4 incongruent triplets. Therefore the test phase had 24 trials (8 (triplets)  $\times$  3 (trials per triplet)) Therefore, there was a total of 144 trials for each condition.

There was also a baseline condition, which was designed to have no predictability of the third picture based on the first two pictures. Therefore, the triplets were all possible combinations using two pictures at each position (see Figure 2-(c)). The goal of the baseline condition was to measure the latency decrease that was due to task familiarity rather than to statistical learning. The total number of trials for the baseline condition was same as the experimental conditions. However, since there were eight unique triplets in the baseline condition, the whole triplet was repeated five times instead of ten. Finally, all conditions had the same number of male and female picture in each position of the triplet, and the frequency of the last picture in each triplet was equated for each condition.

(a) ABABr			(c) Baseline	
learning	test		learning	test
	congruent	incongruent		congruent

X4-N-K	X4-N-K	X4-N-H		

Figure 2: The structure of stimuli in each condition. Every letter represents a picture that was presented sequentially where X denotes a context while other letters denote items.

**Procedure** The experiment consisted of three blocks in addition to the practice block, where each block was assigned to a specific condition (i.e. the ABABr condition, ABCD condition and, the baseline condition). Each block consisted of a learning phase and a test phase, and the transition between learning and test was unbeknownst to the participants while there was a break between blocks. Each participant experienced all four conditions, where the order of the conditions was randomized and the participants did not know the identity of each condition. The procedure of each condition was identical except for the stimuli and the sequence of each stimuli being presented as explained in the stimuli section. Participants were told that they would see cartoon characters and their job was to distinguish whether it was a male or a female. The pictures were presented on the screen until the participants respond, and the next picture was presented after a 750msec ISI. The participants were not informed that there was a triplet structure in each condition. The test phase consist of 4 old triplets from the learning phase and 4 new triplets that where incongruent to the triplets in the learning phase. The order of the triplets was randomized.

After the experiment, participants were asked whether they saw a pattern in the sequence and whether there were any cartoon characters for which it was difficult to determine their sex.

## Results

The results from the post-experimental questions show that all pictures were distinguishable. Moreover, there were no participants who reported finding a pattern in the sequences, thus confirming that learning was indeed implicit.

For the analysis, only the reaction time and accuracy of the third position in the triplet was used. The overall accuracy was 96.48% ( $SD = 2.71\%$ ), with 96.64% ( $SD = 2.69\%$ ) for learning and 95.66% ( $SD = 5.03\%$ ) for test. A  $2 \times 3$  (Phase: Learning vs. Test by Condition: ABABr, ABCD, and baseline) within-subjects ANOVA was conducted on accuracy showed no effect on Phase ( $p = .247$ ), nor Condition ( $p = .220$ ), and no interaction ( $p = .565$ ) (see Figure 3). A  $2 \times 2$  (Congruency  $\times$  Condition) within-subjects ANOVA conducted on the accuracy at test only showed a marginal main effect for Congruency ( $F(1, 79) = 2.95, p = .09, \eta_p^2 = .036$ ), whereas there was no significant main effect for Condition ( $p = .625$ ) nor significant interaction ( $p = .159$ ) (see Figure 4). Conducting a paired t-test between the congruent and incongruent triplets in each condition showed a significant difference in the ABCD condition ( $t(79) = 1.95, p < .05, d = .30$ ) but not in the ABABr condition ( $p = .81$ ).

Before analyzing the reaction time data (RT), values below 250msec and above 2500msec were excluded as outliers. The excluded data was .23% of the total learning data, and .08% for the test data. Also the median value was used for each subject's RT for each repetition in a condition.

The overall mean RT for learning was 577msec ( $SD = 203$ msec), 589msec ( $SD = 190$ msec) for the ABABr condition, 573msec ( $SD = 189$ msec) for the ABCD condition, and 551msec ( $SD = 80$ msec) for the Baseline condition (see Figure 5-(a)). To analyze learning during each condition, the asymptote of each learning curve was calculated. The asymptotic point was chosen by examining the last four repetitions for the experimental conditions and the last two repetitions for the baseline condition (cf. note that experimental conditions of four unique triplets and the baseline condition has eight unique triplets). The median value of each subject's RT was calculated among the asymptotic points and was analyzed using one way within-subjects ANOVA. Results show that there was a significant difference among conditions ( $F(1.95, 154.30) = 3.49, p < .05, \eta_p^2 = .042$ ). Conducting a pair-wise comparison with Bonferroni adjustments showed that the ABABr condition was significantly different from the ABCD condition ( $p < .05$ ), and not different from the Baseline condition ( $p = 1.00$ ). Difference between the Baseline condition and the ABAC condition was also marginally significant ( $p < .10$ ) (see Figure 6).

The mean RT for the ABABr condition at test was 572msec ( $SD = 121$ msec) for the congruent trials, and 563msec ( $SD = 150$ msec) for the incongruent trials. For the ABCD condition it was 543msec ( $SD = 118$ msec) for the congruent trials, and 577msec ( $SD = 162$ msec) for the incongruent trials. The congruent trials for the Baseline condition was 546msec ( $SD = 86$ msec). The analysis of test data suggests that for the ABCD conditions the congruent triplets elicited faster response than the incongruent triplets, which was not the case for the ABABr condition (see Figure 5-(b)). A  $2 \times 2$  (Condition  $\times$  Congruency) within-subjects ANOVA conducted on the test data showed no main effect for Condition ( $p < .518$ ) nor Congruency ( $p < .201$ ), but a significant interaction ( $F(1, 79) = 7.63, p < .005, \eta_p^2 = .088$ ). Further comparison between the congruent and incongruent triplets within each condition was conducted by a paired t-test. Results showed a significant difference in the ABCD condition between congruent and incongruent triplets ( $t(79) = 3.24, p < .005, d = .24$ ). However there was no significant difference between the congruent and incongruent triplets in the ABABr condition ( $p = .534$ ).

In sum, the learning data showed that the ABCD condition had a significant difference in the amount of learning compared to the baseline condition, whereas the ABABr did not. Results from the test data indicated that only the ABCD condition, but not the ABABr condition, exhibited evidence of learning.

## General Discussion

The current study examined the possibility of forming a complex binding structure without attention by presenting participants with an implicit statistical learning task. Results showed that there was evidence of learning only in the ABCD condition but not in the ABABr condition. These findings suggest that whereas forming a two-way binding structure does not require attention, a three-way binding structure does require attention.

The results could be viewed from the point of view of the sequential learning literature (e.g. Reber, 1993) where the conditional probability of the 1<sup>st</sup> item (context item) and the 2<sup>nd</sup> item (item1) in a triplet plays a role in predicting the 3<sup>rd</sup> item (item2). Based on the predictability of each condition,

the ABABr in nature is the hardest condition to learn since the first two items conjointly should predict the third item. This argument is also consistent within the memory literature where a three-way binding structure is required to correctly recall in an ABABr condition - the two cues are conjointly bound with the target item (Humphreys, Bain, & Pike, 1989). On the other hand, the ABCD condition only requires association between the 2<sup>nd</sup> and 3<sup>rd</sup> item, which is also consistent with the memory literature - two-way binding structure.

However, predictability might not be the only factor that plays a role in the ABABr condition. The baseline condition has no predictability since it consist of all possible combinations using binary values at each position of a triplet. Thus, there should be no advantage from predicting the 3<sup>rd</sup> item. However, comparing the ABABr condition and baseline condition at test and learning shows no difference between the two conditions. Since there is evidence that 2<sup>nd</sup> order sequences are learnable (Stadler & Frensch, 1998), learning the ABABr condition should gain from predictability. Therefore, it is possible that the ABABr condition confronts additional interference which could not be alleviated without attention (cf. however, it is arguable that the ABABr condition requires more learning trials.)

The argued binding mechanism has some similarities compared to the binding mechanisms in other fields. In visual perception, binding concerns with object recognition (Treisman, 1996). To recognize an object and differentiate it from others, one should properly bind the properties (e.g. color, shape, location, etc.) to the correct object. Known that different properties are processed in different areas of the brain (Hubel & Wiesel, 2004), correct binding could not be done without attention (Treisman & Schmidt, 1982). Relational reasoning also requires a binding mechanism

(Hummel & Holyoak, 2003), where one has to bind correct fillers (e.g. *cat*, *tiger*) to correct roles (e.g. *B* is **bigger than** *A*) to form a relational representation (e.g. a *tiger* is **bigger than** a *cat*), and to further generalize or infer the representation.

The similarities among these bindings are that incoming components have to be bound together for further processing, and that incorrect binding will produce an erroneous response. However, the level of binding seems to be quite different even though they could be on the continuum. The components in the binding process of visual perception are features that are within the visual object. Moreover, due to dedicated feature detectors the binding process during visual perception would require less elaborated attention than in episodic memory. On the other hand, binding in relational reasoning requires more elaborate attention than episodic memory since the binding structure (i.e. role) is not a simple association but has a specific structure (e.g.  $\sim$  is bigger than). There is no evidence that the binding process has the same underlying mechanism across these domains. However, based on the similarities at the computational level, it is possible that there could be common mechanisms that involve the attentional system.

Finally, the fact that the participants failed to learn in the ABABr condition without attentional mechanism raises a question about the nature of the ABAC condition. Both ABAC and ABABr conditions require a complex binding structure to correctly remember the episode, which is a three-way binding and two two-way binding respectively. In forming a three-way binding structure, one should attend to all three elements that should be bound together. Therefore, attention is critical mostly at encoding but also at retrieval. However, it is possible that the two two-way binding structures are formed as two independent two-way bindings and integrated at retrieval. Thus, attention will mostly be required at retrieval. To address these issues, future studies should utilize methods that could measure attention during encoding and retrieval separately.

## Abstract

Prior research has shown that adults can make rapid use of visual context information (e.g., visual referential contrast and depicted agent-action-patient events) for syntactic structuring and disambiguation. By contrast, little is known about how visual context influences children's language comprehension, and some results even suggest children cannot use visual referential context for syntactic structuring (e.g., Trueswell et al., 1999). We examined whether children (unlike adults) also struggle to use other kinds of information in visual context (e.g., depicted events) for real-time language comprehension. In two eye-tracking studies we directly compared real-time effects of depicted events on children's (Exp1) vs. adults' (Exp2) processing of spoken German subject-verb-object (SVO) and object-verb-subject (OVS) sentences. Both of these word orders are grammatical, but OVS is a non-canonical structure. Five-year olds are at chance in understanding even unambiguous OVS sentences in the absence of visual context (Dittmar et al., 2008). If children can use depicted events rapidly for syntactic structuring, we should find similar visual context effects for them as have been reported for adults (Knoeferle et al., 2005), and similar gaze pattern as for the adults in the present studies. Gaze pattern in the present studies suggested that events depicting who-does-what-to-whom incrementally influenced both adults' and 5-year-olds' visual attention and thematic role assignment. Depicted-event information helped children to get rid of their initial preference for the preferred SVO structure when interpreting OVS sentences. However, visual context effects were subtly delayed in children (vs. adults), and varied as a function of their accuracy and cognitive capacity.

**Keywords:** eye tracking; child language comprehension; visual context; depicted events.

## Introduction

How visual context affects adult language comprehension has been extensively investigated. Adults can rapidly use visual context information such as referential contrast (e.g., Tanenhaus, Spivey, Eberhard, & Sedivy, 1995) and depicted events (Knoeferle, Crocker, Scheepers & Pickering, 2005; Knoeferle, Habets, Crocker, & Münte, 2008) for syntactic structuring and disambiguation. By contrast, for children's use of visual context in (real-time) language comprehension, there are conflicting results (Nation, Marshall & Altmann, 2003; Sekerina, Stromswold & Hestvik, 2004; Snedeker & Trueswell, 2004; Trueswell, Sekerina, Hill & Logrip, 1999; Weighall & Altmann, 2010).

In relating language to visual context, adults' adhere to what's been dubbed the 'referential principle' of language processing: When more than one syntactic analysis is offered

in parallel, the referentially supported (vs. unsupported) analysis is favored. Evidence for this claim comes from a study by Tanenhaus et al. (1995). Participants heard a sentence such as *put the apple on the towel into the box* and inspected related objects (e.g., an apple on a towel, another apple on a napkin, an empty towel, and a box). The prepositional phrase *on the towel* could temporarily either modify *the apple* or (ultimately incorrect) attach to the verb phrase *put*. When two apples (on a towel vs. on a napkin) were present, the phrase *on the towel* permitted adults to rapidly identify which apple the sentence was about, and to avoid a temporary misinterpretation of *on the towel* as the action destination. This was evidenced through eye gaze: adults rapidly inspected the apple on the towel and never the empty towel destination, much like they did for structurally unambiguous baseline sentences (*put the apple that's on the towel into the box*). They thus favored the referentially supported modifier over the referentially unsupported destination interpretation (Tanenhaus et al., 1995).

By contrast, 5-year old children (4;8 to 5;1 years) couldn't use the referential visual context and the underlying referential principle for online parsing decisions when tested with similar visual contexts and sentence ambiguity. In a study by Trueswell et al. (1999), participants either heard a locally structurally ambiguous sentence such as *Put the frog on the napkin in the box* or an unambiguous sentence such as *Put the frog that's on the napkin in the box*. For the ambiguous sentence, the prepositional phrase *on the napkin* can either modify the noun (location) or attach to the verb and specify the destination of the action (destination). Children inspected a table with either only one possible referent for *frog* in the 1-referent condition (e.g. a frog on the napkin, an empty napkin, a distractor and a box) or with two referents in the 2-referent condition (e.g. a frog on the napkin, another frog, an empty napkin and a box).

When 5-year old preschoolers heard the prepositional phrase *on the napkin* in the ambiguous instructions they frequently looked at the incorrect destination (the empty napkin) in both one-referent and two-referent contexts. This was interpreted as indicating that they – unlike adults in Tanenhaus et al. (1995) – incorrectly interpreted this phrase as the destination for *put*. It suggested children did not utilize the Referential Principle to guide their interpretation of the first noun phrase and the ensuing prepositional phrase. Moreover, their actions indicated that they never revised this initial misanalysis: On 60% of the trials the children performed an action that involved the incorrect destination

(e.g., moving a frog to the empty napkin before putting it in the box). The difficulty was attributable to ambiguity rather than structural complexity, since children mostly performed the action correctly (i.e., they moved the frog into the box instead of moving it to the empty napkin) with unambiguous sentences in a 2-referent context if they had moved the target animal first (the frog on the napkin).

The authors attributed the lack of visual context effects to a general inability of children to revise initial commitments made during syntactic structuring and semantic interpretation. Because five-year-old children have more limited processing capacities than adults, it may be difficult for children to make use of the referential principle (in real time) for resolving temporary syntactic ambiguities.

However, Meroni and Crain (2011) found a referential visual context effect in a post-sentence act-out task with a subtly-adjusted experimental design and procedure. Children inspected a two-referent context in which two frogs were placed on different-colored napkins. They were asked to close their eyes while listening to spoken sentences such as *Put the frog on the red napkin into the box*. In this setting, 3- to 5-year-olds exhibited adult-like performance in a post-sentence act-out task (i.e., they moved the frog that was on the red napkin directly into the box). The authors concluded that the changes in experimental setup and procedure enabled young children to inhibit their incorrect syntactic commitment and semantic interpretation. However, they only measured children's performance in a post-sentence task, and not the moment-by-moment processes of children's online language comprehension.

We argue that another reason for the lack of visual context effects in the study by Trueswell et al. may be potential difficulties in using visual referential contrast. Children heard *Put the frog on the napkin into the box*. At the napkin they had a choice in referential processing between looking at the empty napkin (a potential referent for *napkin*) or at the frog that's on the napkin. Since even young children rapidly fixate the picture of a word they have recognized (Hollich, Hirsh-Pasek & Golinkoff, 2000), it may be that children pursue primarily a "referential" strategy when hearing *on the napkin*, and prefer to look at the single empty napkin (vs. another object on a napkin). If children employ such a strategy, it would garden-path them even more since it would direct their gaze to the incorrect destination (the empty napkin). Thus, to the extent that mapping words onto objects (i.e., referential processes) governs child language comprehension, we cannot exclude that the way in which words in the utterance related to objects in visual context, rendered the use of information from that visual context unnecessarily difficult for children.

Related studies have examined the effects of other kinds of information in visual context (depicted action events) on children's comprehension accuracy for difficult-to-understand relative clause sentences (Weighall & Altmann, 2011). Children heard either a center-embedded (*The cat that bumped the bear will hug the cow*.) or a right-branching (*The cow will hug the cat that bumped the*

*bear*.) relative clause sentence. They saw clipart pictures either of the actions described by the relative clause (e.g., an orange cat bumping a bear and a striped cat bumping a sheep) or of several referents but without the actions (e.g. a bear, a sheep, an orange cat and a striped cat). When events were (vs. were not) depicted in visual context, children's accuracy on post-sentence comprehension questions was higher. These findings suggest that visual context can improve children's comprehension of difficult relative clauses and demonstrated that children can utilize extra-linguistic information such as depicted events at least for a post-sentence comprehension task.

Overall and specifically for *real-time* syntactic structuring and thematic role assignment, however, we still know little about how children use events depicting who-does-what-to-whom. We thus examined the effects of depicted events on children's versus adults' thematic role assignment in structurally unambiguous SVO and OVS sentences. Five-year-old children had difficulty in understanding unambiguous non-canonical German OVS sentences (Dittmar, Abbot-Smith, Lieven & Tomasello, 2008), and the same is true for adults (e.g., Matzke, Mai, Nager, Rüsseler, & Münte, 2002). For adults, we already know that for understanding structurally ambiguous or unambiguous OVS sentences, depicted action events can rapidly guide their visual attention and inform thematic role assignment (i.e., shortly after the verb that mediates relevant events, see Knoeferle et al., 2005, Knoeferle, 2007).

Examining effects of depicted events in children is interesting since we don't yet know whether events can rapidly guide their visual attention and thematic role assignment. Furthermore, action events involve a different relationship between the utterance (e.g., a verb such as "pushes") and visual context (e.g., a depicted action and its associated agent) than referential contrast. When children hear the verb – and assuming they incrementally establish reference to objects as has been found – they should rapidly look at the matching action, and notice its associated agent, which could help them to disambiguate / interpret the utterance.

If the lack of a visual context effects in young children results from the complexity of referential contrast rather than children's inability to use non-linguistic visual context, then we should find effects of visual context on thematic role assignment when the content of that visual context has a more direct relationship with words in the utterance (e.g., a verb that can be associated directly with a matching action). Furthermore, the studies by Meroni and Crain (2011) and Weighall and Altmann (2011) only reported children's performance in act-out and comprehension tasks, but not their continuous visual attention during spoken sentence comprehension. Continuous measures such as eye tracking can reveal more about language comprehension in real time. This measure provides a means for examining the moment-by-moment processes of children's spoken language comprehension, in the relatively natural situation of acting out spoken instructions, or answering questions.

To assess visual context effects on children's (vs. adults') processing of German SVO and OVS sentences in depicted event (vs. no-event) contexts, we conducted two eye-tracking studies - one study with children (Exp1) and the other with adults as participants (Exp2). We expected that if children benefit from the depicted events, they would show an adult-like gaze pattern and a higher accuracy in the comprehension task when events are present (vs. absent), particularly for the difficult OVS sentences. In addition, we obtained response accuracy in a post-sentence comprehension task, to ground our interpretation of eye-movement pattern in ultimate comprehension success. We also conducted cognitive tests to get insight into potential variation of context effect as a function of children's cognitive resources. We expected children with higher WM scores would show more adult-like gaze pattern.

## Experiments 1 and 2

### Participants

Thirty-two kindergarten children (15 4-year olds and 17 5-year olds, range: 4-5;10) took part in Experiment 1 and received a small toy for their participation. Thirty-two students of Bielefeld University received four euro each for taking part in Experiment 2. All participants had German as their only mother tongue and normal or corrected-to-normal vision. All were unaware of the experiment purpose. Children, one of their parents (Experiment 1), and adult participants (Experiment 2) all gave informed consent.

### Materials

We created 16 experimental items from 64 clipart pictures edited with commercially available graphics programs, and 64 sentences. An item consisted of four images and sentences. There were two version of an image; one depicted three characters as performing actions ('event', Pictures 1a and 1c, Table 1); the other depicted the same three characters without actions ('noevent', Pictures 1b and 1d). Each image was presented together with either a structurally unambiguous spoken subject-verb-object (Table 1, (1a) and (1a') SVO) or object-verb-subject sentence ((Table 1, (1b) and (1b') OVS)). In recording the sentences we took care to use neutral prosody. The design thus included two within-subject factors: *case marking* (SVO vs. OVS) and *event depiction* (event vs. no-event).

We counterbalanced the event roles of the characters; depiction of actions did not change. For example, one picture (Picture 1a) depicted the bear as pushing the bull, and the worm as painting the bear. The bear in the middle was thus role-ambiguous (agent and patient); the bull was the patient of the pushing action, and the worm the agent of the painting action. On the counterbalancing picture (Picture 1c), the bear was still role-ambiguous but now the worm was the patient of the painting action, and the bull the agent of the pushing action. This ensured visual characteristics of the characters could not confound looks to them as role fillers in an event. The two picture versions were each presented with a SVO and an OVS sentence. Event versus no-event pictures were presented with the same sentences (see e.g., Pictures 1a and 1b in Table 1).

Table 1: Example materials

Picture	Condition	Sentence
1a 	SVO-event	(1a) <i>Der Bär schubst sogleich den Stier.</i> The bear (subj) pushes immediately the bull (obj). 'The bear pushes immediately the bull.'
	OVS-event	(1b) <i>Den Bär malt sogleich der Wurm.</i> The bear (obj) paints immediately the worm (subj). 'The bear is immediately painted by the worm.'
1b 	SVO-noevent	(1a) <i>Der Bär schubst sogleich den Stier.</i> The bear (subj) pushes immediately the bull (obj). 'The bear pushes immediately the bull.'
	OVS-noevent	(1b) <i>Den Bär malt sogleich der Wurm.</i> The bear (obj) paints immediately the worm (subj). 'The bear is immediately painted by the worm.'
1c 	SVO-event	(1a') <i>Der Bär malt sogleich den Wurm.</i> The bear (subj) paints immediately the worm (obj). 'The bear paints immediately the worm.'
	OVS-event	(1b') <i>Den Bär schubst sogleich der Stier.</i> The bear (obj) pushes immediately the bull (subj). 'The bear is immediately pushed by the bull.'
1d 	SVO-noevent	(1a') <i>Der Bär malt sogleich den Wurm.</i> The bear (subj) paints immediately the worm (obj). 'The bear paints immediately the worm.'
	OVS-noevent	(1b') <i>Den Bär schubst sogleich der Stier.</i> The bear (obj) pushes immediately the bull (subj). 'The bear is immediately pushed by the bull.'

We also counterbalanced character orientation to ensure that the role-ambiguous middle character was oriented equally often to the left as to the right for the experiment items. In addition to the 24 experimental items, we constructed 8 filler items. Each filler item had a scene with two characters and a sentence accompanying it. Two started with an adverbial phrase; two with an unambiguously object case-marked noun phrase; two started with a subject case-marked noun phrase; two had two characters doing the same action. Sixteen additional fillers were created for the adults in Experiment 2. Eight of them had the same structure as the fillers in Experiment 1. Of the remaining 8, 4 had pictures that showed three characters doing different actions and 4 depicted only one character. The fillers ensured that the scene did not always depict three characters and that the verb was not always in the second position.

From the four conditions, and their two counterbalancing versions (for character role and orientation, see above), sixteen experimental lists were created, each consisting of 16 experiment and 8 filler items in Experiment 1 (children) and 16 experiment and 24 filler items in Experiment 2 (adults). Apart from the filler trials and the instructions (see Procedure), there were no differences between the child and adult experiments. Each participant saw only one of the four conditions of each item and the same number of items in each condition. Item order was pseudo-randomized individually for every participant. Adults saw at least one filler item in between two experimental trials.

## Procedure

An EyeLink1000 remote eye-tracker with a sampling rate of 500 Hz monitored participants' eye movements. Images were presented on a 22" LCD color monitor at a resolution of 1680×1050 pixels concurrently with the spoken sentences. We only tracked the right eye, but viewing was binocular. In Experiment 1, each child was instructed to play a game. In this game, children were asked to inspect the images and to listen to the sentences. After each trial, they heard a question about the previous sentence and were asked to try to answer it correctly. In Experiment 2, adult participants were instructed to listen to the sentences and inspect the pictures, and to answer the question accurately. For adults, we devised a story to cover our actual goals. The cover story was that the experiment examined how well adults can understand and concentrate on child materials.

Each trial started with the display of a central fixation dot followed by a picture. After a 2000-ms picture preview time, the sentence was played via speakers. Five hundred milliseconds after sentence offset, any depicted actions were removed (if present) and participants only saw the three characters. With only the characters present, a spoken question asked for either the subject or the object of the verb in the previous sentence (for example, *Wer malt hier?/ Wer wird hier gemalt?*, 'Who paints?/ Who is painted?'). Participants answered by naming the correct character. At the start of the experiment, each participant was shown two example images and sentences. Next, participants were set

up and calibrated manually using a five-point fixation stimulus in Experiment 1 and a nine-point fixation stimulus in Experiment 2. The black dot for adult calibration was replaced by a smiley to attract children's attention in Experiment 1. The EyeLink software validated calibration; if validation was poor, calibration was repeated until it was good. Between trials, participants fixated a centrally-located smiley (children) or black dot (adults). This allowed the software to perform a drift correction if necessary. The experiment lasted approximately 25 mins. After the eye-tracking part children completed a working memory (WM) test (a word ordering test; Kaufmann Assessment Battery for Children), and adults were debriefed.

## Analysis

We defined three analysis time windows: the verb region (from verb onset until its offset); the adverb region (from adverb onset until its offset) and the NP2 region (from NP2 onset until its offset). We coded participants' fixations to four areas of interest in the scene: the agent (e.g., the worm in Table 1 Pictures 1a and 1b); the patient (e.g., the bull in Table 1, Pictures 1a and 1b); the role-ambiguous middle character (the bear), and the background. Of those, the agent and patient were our target areas of interest. The proportions of fixation on the target areas of interest (the patient and the agent) were entered into log-ratio analyses (c.f., Arai, van Gompel & Scheepers, 2007; Carminati, van Gompel, Scheepers, & Arai, 2008; Knoeferle, Carminati, Abashidze & Essig, 2011). We computed mean log gaze probability ratios for the agent relative to the patient  $\ln(P(\text{agent})/P(\text{patient}))$  for each condition and time window. Then we entered the log probability ratios into a 2 (*case marking*) × 2 (*event depiction*) repeated measures ANOVA. Separate models were fitted for log-ratios averaged over participants and items. We report the *p*-values of these analyses.

## Results Experiment 1

**Response accuracy** Children's overall comprehension accuracy was 67%. Their accuracy was relatively high for SVO sentences in both the event and the no-event condition (87% vs. 77%). For OVS sentences, by contrast, their accuracy was higher when events were (vs. weren't) depicted (60% vs. 42%). A 2 (*case marking*) × 2 (*event depiction*) repeated measures ANOVA revealed a significant main effect of case marking ( $p < .001$ ) and of event depiction ( $p < .001$ ) by subjects in the absence of a reliable interaction. Spearman's *rho* confirmed that response accuracy was not significantly correlated with age.

**Eye-movement results** Figures 1(a) and 1(b) plot the mean log-gaze probability ratios (participants' means) of correctly answered trials per condition at the verb and adverb regions respectively. For the verb region effects involving the independent variables were not reliable (Fig. 1(a)). By contrast, during the adverb region, children looked more at the patient entity for SVO (vs. OVS) sentences and more at the agent entity for OVS (vs. SVO) sentences, but only

when events were depicted (Fig. (1b)). When there were no depicted events, the eye-gaze data showed that children didn't inspected the correct target object until it was named at NP2 region. Inferential analyses corroborated these effects, as evidenced by an interaction between case marking and event depiction for the adverb region that was significant by subjects ( $p < .005$ ). Thus, case marking at the first noun phrase was not sufficient for incremental thematic role assignment in children; the events, however, enabled correct thematic role assignment. Note that neither case marking nor prosody could account for the different gaze pattern observed in the event vs. no-event conditions since sentences were identical between these two factor levels.

Figure 1: Children's mean log gaze probability ratios ( $\ln(P(\text{agent})/P(\text{patient}))$ ) per condition at the (a) verb region and (b) adverb region for correctly-answered trials in Experiment 1. Positive values indicate more looks to the agent; negative values indicate more looks to the patient.

We further split the subjects into high vs. low groups based on their median accuracy and working memory scores. The interaction between accuracy, case marking and events was significant ( $p < .05$ ), and there was a non-significant trend towards an interaction between WM, case marking and events ( $p < .15$ ). Separate analyses with the high vs. low groups showed that the interaction between case marking and events was significant by subjects for both the high accuracy ( $p < .005$ ) and high working memory groups ( $p < .05$ ) and marginal by items for the high accuracy group ( $p < .1$ ). Response accuracy was significantly correlated with WM scores (Spearman's  $\rho$ ,  $p < .005$ ). Furthermore, there was a hint that children's gaze pattern at the adverb region was correlated with their accuracy data as well (Spearman's  $\rho$ ,  $p < .1$ ).

## Results Experiment 2

**Response accuracy** Adults' accuracy was high (97%). For SVO sentences, their accuracy was 100% in both the event and the no-event condition. Their accuracy for OVS sentences was also high with no reliable difference for the event versus no-event condition (96% vs. 94%). Analyses

confirmed a main effect of case marking ( $p < .005$ ), but not of event depiction and no interaction of these two factors.

Figure 2: Adults' mean log gaze probability ratios ( $\ln(P(\text{agent})/P(\text{patient}))$ ) per condition at the (a) verb and (b) adverb region for correctly answered trials in Experiment 2. Positive values indicate more looks to the agent; negative values indicate more looks to the patient.

**Eye-movement results** Figures 2(a) and 2(b) present the mean log-gaze probability ratios (participants' means) for correct trials per condition at the verb and adverb region respectively for Experiment 2. Adults' (vs. children's) gaze data revealed an even earlier visual context effect, and a reliable interaction of case marking and event was confirmed at the verb (both  $ps < .01$ ). Adults began to look more at the target object for both SVO and OVS sentences at the verb when events were (vs. weren't) depicted (Fig. 2(a)). Figure 2(b) illustrates the continued visual context effects during the adverb, confirmed by a reliable interaction of case marking and event depiction ( $ps < .001$ ).

## Discussion

We assessed how visual context information such as depicted events influences children's online language comprehension and whether children can use visual context for language comprehension to the same extent as adults. To this end we recorded both children's (Experiment 1) and adults' (Experiment 2) eye movements to characters in clipart pictures as they listened to German subject-verb-object (SVO) and object-verb-subject (OVS) sentences. The clipart pictures depicted (vs. didn't depict) who-does-what-to-whom through action events.

The results of Experiment 2 confirm the view that visual context can influence adults' visual attention and sentence processing incrementally and rapidly. Adults looked more often toward the patient character for SVO (vs. OVS) sentences and more often towards the agent character for OVS (vs. SVO) sentences when events were depicted. This gaze pattern replicated the qualitative gaze pattern and its time-course in related adult studies (e.g., effects of case marking and event depiction in Knoeferle, 2007). Not unsurprisingly, effects for the unambiguous sentences in

Experiment 2 occurred slightly earlier (at the verb) than for initially structurally ambiguous sentences (Knoeferle et al., 2005, post-verbally). Adults' response accuracy was expectedly high in both SVO and OVS sentences.

Children's accuracy for the difficult OVS sentences was higher when action events were (vs. were not) depicted (Experiment 1). Thus, action events can improve their comprehension of unambiguous non-canonical OVS sentences for which they are otherwise at chance (Experiment 1 and Dittmar et al., 2008). Unlike suggested by prior results for locally structurally ambiguous sentences (e.g. Trueswell et al., 1999; Snedeker & Trueswell, 2004) we conclude that visual context information can help children to overcome an initial structural (SVO) preference. Future research will address whether our findings extend to locally structurally ambiguous sentences.

Furthermore, effects of the events on children's visual attention and syntactic structuring emerged *incrementally*. At the post-verbal adverb and thus one region before mention of the target entity, 5-year-old children fixated the patient more often when hearing a SVO (vs. OVS) sentence and the agent when hearing an OVS (vs. SVO) sentence but only when action events were depicted. Children's gaze pattern during the adverb suggests that visual context information (depicted agent-action-patient events) can rapidly influence their sentence processing and syntactic structuring for unambiguous but non-canonical sentences.

The interaction of case marking and event in the high (but not low) WM and accuracy groups suggests that visual context effects are sensitive to children's cognitive capacities and that they may co-vary in their emergence with increases in cognitive resources. Overall, however, visual context information can inform syntactic structuring and thematic role assignment incrementally and rapidly in both 5-year old children and adults.

## Acknowledgments

This research was funded by the Cognitive Interaction Technology Excellence Center (German research foundation, DFG) and a Fulbright fellowship to LK. We thank Linda Krull and Eva Mende for help with stimulus preparation and data collection; Maria Nella Carminati for advice on the analyses; and Helene Kreysa for advice on the Experiment Builder software. We also thank all the participating families and students for their support.

# Argument Homogeneousness and Structure Simplicity

Niina Ning Zhang (Lngnz@ccu.edu.tw)

Graduate Institute of Linguistics, National Chung Cheng University  
168 University Rd., Min-Hsiung, Chia-Yi 62102 Taiwan

## Abstract

Subjects and objects are arguments of verbs. They show either homogeneous or heterogeneous properties, with respect to time. The subject of *sleep* and the subject of *fall* are homogeneous and heterogeneous, respectively. In this research, we develop a novel analysis of the organization of arguments of various types of verbs. We argue that heterogeneous arguments are hosted in two levels of Verb Phrase, whereas homogeneous ones are hosted in one level of Verb Phrase. Therefore, homogeneous events and states are encoded in simpler syntactic structures than heterogeneous ones in natural language.

**Keywords:** argument; verb, syntax; language, simplicity; homogeneous; heterogeneous; transitive; intransitive.

## 1. Introduction

The goal of this study is to try to explore the cognitive view that different conceptualizations will lead to different syntactic structures and that the complexity of the former should correlate with the complexity of the latter. This study develops Klein's (2010) new theory of the arguments of verbs and proposes a novel analysis of the structures of the arguments of various kinds of verbs. Instead of the traditional triple division of transitive verbs (e.g., *kiss*), unaccusative intransitive verbs (e.g., *arrive*), and unergative intransitive verbs (e.g., *sleep*), we argue that verbs are first divided into homogeneous and heterogeneous ones, and then each type is further divided into transitive and intransitive subtypes. The two major types are different in the number of Verb Phrases (VPs) are involved in the syntactic structures: homogenous ones have only one-layer of VP, while heterogeneous ones have two-layers of VP. Therefore, in our understanding, homogeneous events and states are encoded in simpler syntactic structures than heterogeneous ones.

We will introduce a new classification of verbs based on Klein (2010), then present our proposal, in Section 2 and 3, respectively. In Section 4, we list our supporting facts. Finally, in Section 5, we make some general remarks about this new syntactic analysis.

## 2. Classification of Verbs

Based on the homogeneousness of the properties of an argument with respect to time, Klein (2010) discusses certain types of verb stems in their default readings. As pointed out by an anonymous reviewer, Klein's term time should be understood as state. I thus use the term state rather than Klein's term time. There are one-state arguments, which are homogeneous in the event or state, such as the subject of *laugh*. There are also two-state arguments, which

have a source state and a target state, and thus they are not homogeneous in the event or state, e.g., the subject of *fall*.

Homogeneous Intransitive (HOI) verbs have one argument with respect to one state, e.g., *sleep, dance, vibrate, be*.

Homogeneous Transitive (HOT) verbs have two arguments with respect to the same state over time, e.g., *weigh* with a measure phrase, *resemble, admire*.

Heterogeneous Intransitive (HEI) verbs have one argument with source time state and target time state, e.g., *die*, (intransitive) *drown, rise, remain*.

Heterogeneous Transitive (HET) verbs have two arguments — one at one time state, one with source time state and target time state. The state of the one-time state argument can overlap the source or target time states of the other argument, e.g., *leave, close, slay*, (transitive) *drown, observe*.

We summarize the classification in the following table (AS = Argument-State; Ss = source time state; St = target time state):

(1) Common AT-structures (cf. Klein 2010: 1231)

type	description	typical examples	AS skeleton
HOI	1 argument at one state	<i>sleep, dance, vibrate, be</i>	A   S
HOT	2 arguments at the same state	<i>weigh</i> with a measure phrase	A1 A2 \ S
HEI	1 argument with source state and target state	<i>die</i> , (intransitive) <i>drown, rise, remain</i>	A \ Ss St
HET	2 arguments—1 at one state, 1 with a source state and a target state.	<i>leave, close, slay</i> , (transitive) <i>drown, observe</i>	A1 A2   \ Ss St

## 3. The Structure-Positions of Arguments

A well-adopted assumption is that all verbs are represented by a two-layer verbal projection: a vP to host the external argument of a transitive verb, or the unique external argument of an unergative verb, and a VP to host the internal argument of either a transitive verb or an

unaccusative verb. The assumption does not consider the contrast between HO and HE verbs at all. All external arguments are assumed to have the same syntactic position, i.e., Spec of vP.

We propose that arguments of the four types of verbs are base-generated as in (2).

- (2) a. HOI: [<sub>VP</sub> V Argument]

- b. HOT: [<sub>VP</sub> Argument 1 [V Argument 2]]

- c. HEI: [<sub>VP</sub> v [<sub>VP</sub> V Argument]]

- d. HET: [<sub>VP</sub> Argument 1 v [<sub>VP</sub> V Argument 2]]

One can see that HE verbs have vP, whereas HO ones do not, regardless of how many arguments occur. In (2b), the two arguments are hosted in the same VP; but in (2d), the two arguments are hosted in vP and VP, respectively.

In the structures for HO verbs, only one-layer of VP is projected, and there are maximally two positions for arguments: one is at Spec and the other is at Complement of V. In contrast, in the structure for HE verbs, there are two layers of VP, and thus one more position is available for an additional argument.

## 4. Supporting Facts

Three kinds of evidence supports our proposal in (2): the integrity of the verbs and the arguments of HO

constructions (4.1); the structural richness of HE constructions (4.2); and the special contrasts between HO and HE verb constructions (4.3).

### 4.1 Structure Integrity

All of the arguments that support severing the subject from VP or projecting of a vP shell (Marantz, 1984; Larson, 1988; Kratzer, 1996) come from HE, rather than HO, constructions. Typical tests are pseudo-cleft and the do-so replacement.

**4.1.1 Pseudo-cleft** Unlike HE verbs, HO verbs fail in pseudo-cleft (Zucchi, 1998: 349) (\* means the sentence is not acceptable).

- (3) a. What John did was eat an apple. [HE]  
b. \*What John did was resemble his father. [HO]

**4.1.2 vP-proform *do so*** Unlike HE verbs, HO verbs fail in replacement by the vP-proform *do so* (Ross, 1970; cf. Stroik 2001: 367).

- (4) a. Chris is leaving now, and Sam is doing so too. [HE]  
b. \*Mary likes Sam, and Chris does so too. [HO]  
c. \*The shoes cost 5 dollars, and the gloves do so too. [HO]

The two restrictions on HOT verbs are covered by (2b), where the whole VP is composed of two arguments and the verb. In the structure, the combination of V and Argument 2 is just part of a VP, which lacks syntactic visibility (Chomsky 1995). The combination is not a vP, either, since vP does not exist for this type of verbs. Therefore, it may not be replaced by *do so*.

### 4.2 Structure Richness

HE constructions have more argument positions than those of HO constructions. This can be seen in the following four facts.

**4.2.1 Double object constructions** Why is there no double object or applicative HO verb (5)? If only HE verbs may host their arguments in two layers of VP, the contrast is explained. (2b) does not have enough positions for three arguments.

- (5) a. I gave him the clothes. (HET)  
b. \*I like him the clothes. (HOT)  
Intended: 'I like him with respect to his clothes.'  
(6) a. John rented Bill a room. (HET)  
b. \*John resembles Bill the eyes.  
Intended: 'John looks like Bill with respect to their eyes.'

**4.2.2 Object control constructions** There is no HO object-control construction, which has two internal arguments: a nominal and a clause.

- (7) a. Mary forced John to feed the baby.  
 b. \*Mary admired John to feed the baby.  
 Intended; 'Mary admired John for his feeding of the baby.'

**4.2.3 Expansion from HO to HE constructions** Many verbs may occur in either HO or HE constructions (e.g. Dowty 1979: 60; Rosen 1999). It is easy to change an otherwise HO construction into a HE one by adding a delimitable element. But we do not add material to a HE structure to change it into a HO one (Thompson 2006: 218). HE structures are thus richer than HO ones.

(8) ADDITION OF DIRECT OBJECT

- a. Bill ran (\*in 5 minutes). [HO]  
 b. Bill ran the mile in 5 minutes. [HE]

(9) ADDITION OF INDIRECT OBJECT

- a. That book costs three dollars. [HO]  
 b. That book has cost me three dollars. [HE]

(10) ADDITION OF COGNATE OBJECT

- a. Terry sang (\*in an hour). [HO]  
 b. Terry sang the ballad in an hour. [HE]

(11) ADDITION OF X'S WAY EXPRESSION

- a. Terry sang (\*in an hour). [HO]  
 b. Terry sang her way to the Met in 10 years. [HE]

(12) ADDITION OF FAKE REFLEXIVE

- a. Terry sang (\*in an hour). [HO]  
 b. Terry sang herself to sleep in an hour. [HE]

(13) ADDITION OF RESULTATIVE

- a. Terry ran (\*in an hour). [HO]  
 b. Terry ran us ragged in an hour. [HE]

Note that heterogeneous events can be repeated (*Mary dried the dishes in an hour.* vs. *Mary dried the dishes for hours before being released from duty*) (Thompson 2006: 218; Ramchand 2008: 31). It is just like all nominals can be counted if an appropriate unit is identified (*two drops of water* as well as *two books*).

**4.2.4 Verb affix marking** Certain formatives mark the HE status of the verb, and their absence marks the HO status, e.g., *meg-* in Hungarian (Hopper & Thompson 1980: 267) (O means object):

- (48) a. *A gazda MEG-verte az inasokat.*  
 the boss PERF-beat(OBJ) the apprentices(ACC)  
 'The boss beat the apprentices.'  
 b. *A gazda verte az inasokat.*  
 the boss beat(OBJ) the apprentices(ACC)  
 'The boss would beat the apprentices.'

With the prefix *meg-* (Hetzron's 'effective aspect'), 48a means that the boss did beat all the apprentices on one occasion; the action is thus perfective and punctual, and the object is totally affected. But 48b, without *meg-* (Hetzron's 'descriptive aspect'), means that the boss was not above beating the apprentices, that he did it from time to time, but that not all the apprentices were necessarily involved; the action is claimed, then, to be imperfective and iterative, and the O is not totally affected.

From the above citation, we can see that the event reported in (48a) is bounded and thus the sentence is a HE construction, whereas the event reported in (48b) is unbounded and thus the sentence is a HO construction. Presumably, formatives such as *meg-* are licensed by vP, and thus the HE reading correlates with a richer structure.

**4.3 Special Contrasts Between HO and HE Verbs**

Three further contrasts between HO and HE verbs are reported as below.

**4.3.1 Intransitive verbs exhibit HO-HE contrasts** Only HEI verbs allow the expletive *there*, but HOI verbs may not, as seen in (14).

- (14) a. There arrived a train in the station. [HE]  
 b. \*There laughed a man in the hallway. [HO]

This contrast can be captured by the assumption that the expletive is base-generated in vP only (Deal, 2009). (2c), but not (2a), has vP, although both are for intransitive verbs.

**4.3.2 Transitive verbs exhibit HO-HE contrasts** We have seen the contrasts between HOT and HET in English in (4). Moreover, in some languages (e.g. Finnish, Hungarian) only HE structures have accusative case marker. The following Finnish examples are cited from (Hopper & Thompson 1980: 262):

- (15)  
 a. *Liikemies kirjoitti kirjeen valiokunnalle.*  
 businessman wrote letter (ACC) committee-to  
 'The businessman wrote a letter to the committee.'  
 b. *Liikemies kirjoitti kirjettä valiokunnalle.*  
 businessman wrote letter (PART) committee-to  
 'The businessman was writing a letter to the committee.'

In (15a), the presence of the ACC (accusative) marker with the direct object *kirjeen* 'letter' indicates a bound event: a letter was created at the target time, and thus the event was not homogeneous. In (15b), however, there is no ACC marker with the direct object, and the event could be homogeneous. See Rosen (1999) for more such examples.

The contrast can be captured in the contrast between (2b) and (2d): the overt accusative case marking is licensed by vP (cf. Chomsky 1995). Only in (2d), which is for HET, vP is projected and thus the ACC marker can be licensed. Since

there is no vP in (2b), which is for HOT, no ACC marker can be licensed in the structure.

**4.3.3 The prefix *re-*** Certain rules apply to HE constructions only, but not HO ones, regardless of whether the verb is transitive or intransitive. The English prefix *re-* occurs with HE verbs only, as seen in (16) (Horn, 1980). Since *again* behaves differently, the issue is not semantic.

- (16) a. The door reopened. [HE]  
 b. I reopened the door. [HE]  
 c. John {\*resmiled/smiled again}. [HO]  
 d. \*John re-admired his father. [HO]

Note that *re-* scopes over either the HE root or the affected nominal (Marantz, 2005). But the ambiguity is independent of the HE restriction.

**4.3.4 The time frame preposition phrases** Preposition phrases like *in an hour* are licensed by HE verbs, regardless of whether the verb is transitive or intransitive, as seen in (17). Thompson (2006) shows that such PPs are licensed by a projection higher than VP. Their absence in HO constructions indicates that the structure of HO constructions are lower and thus simpler than that of HE ones.

- (17) a. John walked to the store in two hours. [HE]  
 b. John destroyed the toy in two hours. [HE]  
 c. \*John slept in two hours. [HO]  
 d. \*John admired his father in two hours. [HO]

## 5. General Remarks

In this proposed new analysis of the time-argument structures of various types of verbs, the structures of homogeneous eventuality constructions are simpler than those of heterogeneous ones.

A parallel analysis of noun constructions is found in Borer (2005) and Zhang (2012). In Borer's analysis, CLP or DivP is projected for count nominals, but not for mass nominals. In Zhang (2012), DelimitP is projected for non-mass nominals, but it is absent in the structures of mass nominals. In both analyses, the structures of mass nominals are simpler than those of count nouns. The former shows homogeneousness, whereas the latter does not.

The significance of this study is that, like Borer's (2005) and Zhang's (2012) studies of nominal structures, our research of verbal structures here also show that the perceived homogeneousness in our understanding of the world, including events and individuals, correlates with the simplicity of linguistic structures.

## Abstract

We investigate how cognitive capacity limits the number of group relations that a person can maintain. The simulation experiment's results using ACT-R and its memory equations replicated an effect similar to that of Dunbar's (1998) number, or the average total number of group ties capable of being supported in memory. In our study, we also examined the influences of two spatial factors (navigation strategies and map configurations) on the growth of generative networks. Our results suggest three interesting conclusions: (a) a fixed-path navigation strategy increases the speed that networks can form; (b) a higher *grid ratio* (connectivity of the agents' world) provides more chances for agents to build relations, and thus increases the network generation speed; but (c) neither factor influenced the total relations that an agent could maintain, which implies that Dunbar's number primarily depends on internal cognitive factors and less on external factors.

**Keywords:** ACT-R, Cognitive modeling, Social-cognitive network, network formation.

## Introduction

What does it mean to know someone? In colloquial English, this can imply anything from knowledge of someone's true character or secrets to a casual friendship. Nevertheless, this kind of knowing seems to imply more than a declarative association. I may know that Michelle Obama is Barrack Obama's wife, but I cannot say that I know either Michelle or Barrack Obama. Knowing in this context seems to imply knowledge not only of an individual's identity but also some knowledge of the significant relationships in their life, knowledge derived from direct interactions with that individual. I may get to *know of* Barrack Obama by reading his memoir but I get to *know* him in a social sense by speaking with him.

In this paper, we begin to explore what it means to know someone in a network, and how that knowledge influences our daily interactions. Drawing from Simon's (1991) work on bounded rationality in organizations and Dunbar's (1998) work examining the connections between cognition and language, we believe this form of knowledge reliably constrains organizations and moderates our behavior. Consequently, we seek to identify more concretely the mechanisms that underlie tie-formation, in other words the foundations of friendship. We begin by modeling the rate of tie formation in cognitively plausible generative networks.

Dunbar (1998) presents empirical evidence that suggests that human social networks are cognitively constrained. Chiefly, he argues that the neocortex size of humans limits the size of a fully connected human social network to about 150 ties. He defines a fully-connected social network as one

where all members can not only attach an identity but also a relation to all other members (Dunbar, 1998, pp. 66-68). He further argues that this constraint underlies the small-world effect observed by Milgram (1967) and others. He distinguishes this number of group ties from the number of sympathy ties, the number of intimates a person encounters in a month ( $n=11-12$ ), or the number of face-to-name matches a human can typically perform ( $n=1,500-2,000$ ). Dunbar infers these numbers and the relationship between neocortex size and social network size from empirical studies of human and non-human primates. He then compared these findings with anthropological evidence, finding his predictions basically matched the anthropological data.

McCarty, Killworth, Bernard, Johnsen, and Shelley (2001) propose a far larger number ( $n=291$ ) as an average network size. In part, this discrepancy is rooted in a difference in definitions. McCarty et al.'s (2001) definition of a social tie requires mutual identification as opposed to Dunbar's stricter definition of mutual identification and placement in the network. Also, McCarty et al. suggest other possible sources of discrepancy such as responder biases (number preferences and individual differences), size effects that influence the respondents' ability to accurately estimate the number of acquaintances associated with either very small or large subpopulations, and analysis errors arising from missing data or numerical biases introduced when combining studies. Nevertheless, neither of these potential sources of error nor the difference in definition seem to entirely account for the wide discrepancy in these estimates because, while McCarty et al. allude to ecological effects, neither they nor Dunbar systematically account for them. Also, it remains an interesting question as to what extent the difference in definitions contributes to the difference in estimates.

Ecology (defined here as an actor's physical and social environment) influences cognition not only by presenting a set of opportunities and resources but also by moderating our perceptions of those opportunities (Brantingham & Brantingham, 1993). We also know that humans are sensitive to environment when recalling sets of relations, using different approaches in different settings (Metz & Shultz, 2010). There has been far less work, however, examining to what extent ecology reliably influences tie formation in memory. For instance, one criticism of Dunbar's estimate is that it does not include the significance of environmental complexity. In other words, would the number of social ties, as Dunbar defines them, ever emerge in a distributed social structure like Suburbia, or could it? Does neocortex size impose a maximum, or is the relationship more complex?

More generally, how does memory and environment mediate and constrain social networks?

We begin to examine these questions by modeling the effects of memory on the formation of generative networks (networks arising from an initially empty set). We use McCarty's et al.'s (2001) definition of ties, that is, identification is sufficient to constitute a tie in this experiment. We believe that understanding the rate of network formation is a necessary precondition for reconciling Dunbar's and McCarty et al.'s estimates because this rate, in itself, constrains the opportunities available in the social set. In other words, the rate of network formation influences the emergence of in-and-out group dynamics which in turn mediates the formation of all subsequent groups (Festinger, Schachter, & Back, 1950).

Agent-based simulations have been used for social network studies for many years now. Carley and Newell (1994) were, to our knowledge, the first to use a cognitive architecture (Plural Soar) to study organizations. More recently, some studies have applied cognitive architectures to model human decision making in collaborative tasks (Lebiere, Gonzalez, Dutt, & Warwick, 2009; Morgan, Morgan, & Ritter, 2010; Prietula & Carley, 2001). These authors have, however, primarily focused on small group collaborations and interactions with less than 20 agents.

In this paper, we use a cognitive architecture based socio-cognitive simulation to examine the effect that memory activation thresholds, navigation strategies, and map-configurations have on the rate of network formation. Examining different memory activation thresholds for links between agents enables us to model not only the effects of memory retention on network formation but also provides us a means of representing differences in the modeled social ties' *quality*, as Dunbar defines this term (Dunbar, 1998, pp. 76-77). In other words, higher quality relationships are associated with greater cognitive investment and higher memory strength. Comparing navigation strategies and map configurations allows us to represent the social opportunities associated with activity spaces in the environment.

This study draws from previous work (Kaulakis et al., 2012) and (Zhao, Kaulakis, Morgan, Hiam, & Ritter, 2012). In Kaulakis et al.'s, we introduced an earlier version of an ecological model and modeling environment (VIPER). Kaulakis et al.'s presents a structural analysis, examining how the agents' declarative representation of their social ties reliably differed from the experiment's ground truth network, or the network formed from all the agents' room co-occurrences. Kaulakis et al. found population size had the greatest influence on network construction in memory, but that the similarity results were tentative. Zhao et al. (2012) elaborated on the model by adding navigation strategies. Zhao et al.'s primary contribution, however, showed that parameters in the simulation, world size, length of interactions, and navigation strategies, led to changes in the agents' average activation values in their social networks. While promising, these studies provided no

insight as to the rate of network formation and did not examine Dunbar's number in detail.

To reconcile Dunbar's (1998) and McCarty's et al.'s (2001) estimates, we need to understand time not only as defining all the possible social opportunities available to the network but also how previous tie formation constrains future choices. To do this, we first need some notion of a simulated network's formation baseline, when in other words does the network reach equilibrium and its members are primarily maintaining in memory as opposed to making ties? We examine this question here.

## Experiment Environment

To model multi-agent social behavior, we constructed a simulation environment, VIPER. All of our experiments were conducted on a 2GHz eight-core Linux 2.6.31 machine with Ubuntu 11.04 with 8GB of RAM, with SBCL 1.0.52 as our Lisp. We use ACT-R 6 in Anderson et al. (2004).

### ACT-R

ACT-R (Anderson et al., 2004) is a cognitive architecture and unified theory of cognition. It tries to provide a fully functional system that produces all aspects of human behavior at the cognitive level. We use ACT-R because its memory mechanisms enable us to fully implement the cognitive capacities and constraints we believe necessary to model the emergence of networks.

### VIPER

VIPER, a text-based multi-agent simulation, models physically embodied social networks (Kaulakis et al., 2012). It is designed to support multi-agent simulations used to study network science. It is lightweight in that it is text based, but is extensible and records agent behaviors over time to support studies on how networks form. VIPER represents these constraints in several ways, the chief being a strong separation between the agents and their environment. VIPER is dynamic, agent-based, and designed to be a part of a distributed model that resolves events in either real or accelerated time.

To handle large amount of agents simulation, we utilized file imaging techniques in Linux system to reduce the memory cost of ACT-R. This reduces the cost of a single ACT-R thread from 50 Mb to less than 20MB, which allows us to run 1,000 agents on one machine.

## Experiment

To explore the effects of environmental connectivity, navigation strategy, and memory activation thresholds on the pace of network formation, we ran a simulated study that examined each of these three factors.

### Map Configuration

Drawing from work in environmental psychology and crime mapping, we know environmental complexity influences network formation; we represent environmental complexity

with three room configurations. We measure the relative connectivity of our three map configurations by defining its *grid ratio*, the ratio of the number of edges over the total number of edges possible for a rectangular grid containing the same number of rooms.

We used three map configurations, shown in Figure 1. The first configuration (Figure 1a) is a two-hallway configuration with *grid ratio* 0.6. This configuration should lead to low connectivity due to the large distances between the agents. The second configuration (Figure 1b) has a central area with *grid ratio* 0.75. We predict that Figure 1b's central meeting point will lead to network connectivity that is less than that found in Figure 1c but greater than that found in Figure 1a. The last configuration (Figure 1c) is a full 5x5 grid with *grid ratio* 1.0.

Figure 1: Maps (hallway, central, full grid) used in the simulation study.

### Navigation Strategies

In a social network the agents' movement patterns will influence the social network's topology by again influencing any one's agent's interaction opportunities. For example, a policeman walking beat will likely have a larger number of acquaintances than a person who spends most of his or her time at home because the policeman has more opportunities to meet people. To replicate human navigation behavior, we implemented two navigation strategies: random-walk and fixed-path.

- 1) *The Random-walk strategy* implements a random walk.
- 2) *The Fixed-path strategy* follows a specific path to navigation in a small area. This strategy simulates the routine navigation behavior, such as going work or going to school.

### Experiment Parameters

Zhao et al. (2012) found that the map configurations and navigation strategies influence network measures. In this experiment, we will examine the two navigation strategies for each of the map configurations in 4 runs. The total agent size is currently an arbitrary choice, 40; forty provides a populated but not crowded environment to study. The parameters of the 4 runs are shown in Table 1.

Table 1: Setting of experiment parameters

Runs	Agent size	Map configuration	Navigation strategy
Run 1	40	Hallway	Fixed
Run 2	40	Hallway	Random
Run 3	40	Central	Random
Run 4	40	Grid	Random

To examine the growth curve of the network, we captured the network growth over 18 time slices between 10 and 500 s. Those sample running times were selected by running a pilot experiment, from which we found that the curve changes significantly from 80 to 150 s. We present more sample times here, resulting in a more interesting and precise curve.

## Results and Analysis

We examine the effect of the three parameters (map connectivity, navigation strategy, and memory threshold) in order. Each run took approximately 500 seconds in real-time, with the analysis logs being analyzed by hand using ORA (Carley, Reminga, Storrick, & Columbus, 2011).

### Memory Networks

With 4 runs and 18 sampling times, we created 2,880 egocentric memory networks (one for each agent, noting who that agent thought they knew, as shown in Figure 2a), and 72 merged memory networks across a run of 40 agents (merging memories across agents in a run, as shown in Figure 2b). Both networks in Figure 1 consist of agents where no memory threshold was applied.

Figure 2: Example egocentric network (left) and merged memory network (right) for agents without a memory threshold applied.

### Curves of the Growth of Merged Networks

In this section, we show the effects of the model's three parameters on the rate of tie formation. Based on these figures, we will discuss how memory thresholds, map configurations, and navigation strategies influence the formation rates of simulated networks.

Figure 3 shows the growth curve of a network consisting of agents using a fixed-path navigation strategy in the Hallway map. The lower line represents the network formation rate of a network where no memory threshold was applied—if an agent met an agent, they formed a permanent tie. We find that the lower curve increase rapidly and then

flattens when it reaches 1,336 ties (the maximum is  $40 \times 39$ , or 1,560, if the agents' paths completely overlap, which they do not). This flattening occurs once the network has achieved equilibrium and is fully connected.

In Figure 3, the top solid line represents the network formation rate of a network where an activation threshold of 0.0 was applied. According to the ACT-R theory, the activation threshold represents a memory limitation, meaning that memory chunks with an activation value lower than the threshold cannot be retrieved. The top curve's more gradual progression illustrates the influence of memory on the formation rate, multiple exposures are required to remember another agent. While the difference in total number of links (800 versus 1,336) illustrates memory's effect on the network's topology. In addition, this network never achieves a fully connected state, in the sense that the agent's declarative representation at no point includes the total set of possible interactions. In other words, these agents must continue to maintain their relationships because they continue to forget. Nevertheless, this networks does eventually acheives equilibrium at 150 seconds with a network size of 800 links.

Comparing the two solid curves in the Figure 3, we noticed another difference, the time at which the rate of growth begins to increase. For the thresholded network, this time happens later than for the un-thresholded network. This is because the agents tie formation requires multiple exposures. Initially, agents are busy simply encountering other agents and building their friends list. As they, however, begin to meet more "old friends", the activation values of friendships start to increase. The dash curve in Figure 3 shows the number of relations that could not be retrieved. The curve grows fast at the beginning because most of new ties are weak and un-retrievable. It decrease after 200seconds as the network acheives equilibrium.

The x-axis of the Figure 3 represents the simulation running time in real seconds. In our experiment, we set the traval interval between rooms at 16 seconds to make the effect of memory decay more prominent. Nevertheless, this interval is still not long enough to be realistic because people might take minutes or hours to find another person. As this work only focuses on the growth pattern of the social network, we would argue that the measurement of time is a secondary factor of our study because over 80 percent of the decay happens in the first 16 seconds acording to the ACT-R decay equation, with little additional decay occouring at greater time scales. Consequently, we believe total running time of 500 seconds and a short travel interval of 16 seconds are acceptable for simulating the growth pattern.

Figure 3: The effect of memory threshold on network formation over time for the fixed path navigation strategy in the hallway map.

Figure 4 shows the growth curve of a network of agents using the random navigation strategy in the Hallway map. Comparing Figure 4 with Figure 3, the non-threshold curves have the same growth pattern, but the threshold curves appear to be different. Memory appears to have different effects based on the setting in which the agents operate.

Figure 4: The effect of memory threshold on network formation over time for the random walk strategy in the hallway map.

Figure 5 compares the growth curves of two networks where a memory retrieval threshold of 0.0 was applied; these networks differ with respect to the navigation strategy used by their members. The fixed path-strategy (dash line) forms ties more quickly than the random-path strategy. We suspect that the fixed-path strategy achieves equilibrium sooner because it is more localized, and thus provides more chances for agents to meet their "old friends". On the other hand, both networks achieve equilibrium at about 800 links, suggesting that the navigation strateies in this simulation do not constrain the number of relations an agent can maintain in memory.

Figure 5: The effect of navigation strategy on network formation over time in the hallway map with threshold.

Figure 6 compares the network formation rates of networks occurring in each of the three map configurations (full grid, central, and hallway); all these networks consist of agents with a memory activation threshold of 0.0. We find that the map configurations have a similar influence on the networks' growth curves as the navigation strategies. Again, the map configurations influence the rate of formation but not the network's size at equilibrium.

Figure 6: The effect of map configuration on network formation over time.

Comparing the three curves, we find the Hallway map (*grid ratio*=60%) is associated with the longest delay in network formation and the lowest rate of increase; the full grid map (*grid ratio*=100%) has the shortest delay and the fastest rate of link formation. These results show that delay in the network's growth rate is negatively correlated with *grid ratio*, while the network's growth rate during its growth spurt is positively correlated.

### Activation Normalization: Semantic Challenges

One of the main issues we face in the analysis and interpretation of our results is the need to assign semantic meanings to the activation values associated with our ACT-R agents' memory chunks. Because raw activation values may grow or shrink indefinitely, we see normalization as a process by which the data can be made more regular, and to help scale between time scales used in our simulation and those occurring in the real world.

In the introduction to this paper, we cited Dunbar's (1998) concerns about tie "quality". In this work, we used raw activation values in our measures, which is fine for our purposes, but is insufficient for many other questions. Activations are not portable or easily interpretable in social terms. To make sensible translations between activation levels and Dunbar's notion of tie quality, we suggest that the ties be normalized as we describe in this section. This normalization recasts activations as statements about the "probability of recall" within a particular timeframe. Using activations in this way supports the measurement of environmental parameters, and the prediction of environmental distractions that are likely to prevent tie consolidation by limiting the time available for tie maintenance. This grounding provides metrics that are empirically measurable and come closer to Dunbar's "quality" concept. Derived from the ACT-R Probability of Recall Equations (Anderson et al., 2004), where the

normalized activation value is a function of three variables internal to the agent, such that  $i$  is the current chunk,  $\tau$  is the threshold for recall, and  $s$  is noise, then the normalized value is a probability that a particular chunk will be recalled:

$$A_P(i, \tau, s) = \frac{1}{1 + e^{\frac{-(A(i) - \tau)}{s}}} \quad (\text{eq. 1})$$

This method fulfills all of the requirements above and provides a concrete interpretation of activation levels as Probabilities of Recall. Additionally, it also ties the threshold to the time of recall in seconds, like this:

$$T_i = F e^{-A_i} \quad (\text{eq. 2})$$

These properties will make the analysis of normalized activation values able to generate much stronger statements about the settings in which the agents live.

### Conclusion and Discussion

This study simulated an effect like Dunbar's number on networks of cognitive architecture-based agents. The first analysis examined to what degree **cognitive limitations** (represented by a memory activation threshold) influenced the generative process of a network. *The results suggest that cognitive limitations influence both the rate of network formation and the size of the network at equilibrium.* These findings roughly mirror what is found in empirical studies (Brantingham & Brantingham, 1993).

We can view the progression of the curves in Figures 3-6 as corresponding to three stages in network formation, though at abbreviated time scales. Between 0 and 100 seconds, the size of the network does not grow significantly, and the average number of relations stays constant at 60. This represents the tendency of people to initially remain in localized relations with a few people. During this period of the simulation, the non-thresholded network grows very fast (becoming fully connected at 100 seconds) because most the agents wander around to meet new friends and initialize new relationships. For the thresholded networks, there is greater period of latency because the agents have not yet had the time to consolidate their friendships, but rather are primarily building their friends list. Between approximately 100 to 150 seconds, we see that thresholded networks begin to rapidly increase in size as the agents become more familiar with the activity space. Finally, between 150 to 500 s, the thresholded networks stop growing because the agents have shifted from primarily establishing to maintaining their friends network. In the stable state, the number of total links remains around 800, meaning that the average number of relations per agent in these networks is about 20.

In the second analysis, we examined the influences of two **navigation strategies**. The results suggest that navigation strategies have little influence on the non-thresholded network but for growth time, and it does change the growth speed and pattern of the thresholded network. In Figure 5, we see that the network using the fixed-path strategy grows much faster. This is because the fixed-path strategy is a more focused strategy that provides more chances for

people to meet their “old friends”. In this case, people more easily form small groups associated with their starting location, such as people living on the same street or attending the same school. *We see that the fixed-path strategy facilitates the rapid creation of smaller tighter groups than the random-walk strategy.*

The third analysis focused on examining the influences of **spatial configurations** on generative networks. We defined *grid ratio* as the ratio of the number of edges over the total number of possible edges to quantify the connectivity of the map configurations. We find that delay increment is negatively correlated with *grid ratio*, while the formation rate during the growth phase is positively correlated with the *grid ratio*. This result validates our definition of *grid ratio*, because it shows the *grid ratio* does have influence on network formation; it also proves that lower *grid ratio* maps with more gaps and obstacles decrease the network’s growth rate. *We found, however, that our map configurations did not influence the final size of the network.*

Summarizing our results, we see that navigation strategies and room configurations only seem to significantly influence our networks’ delay increment and growth rate, while the final size of our thresholded networks remains at 800 links. We suspect that one possible way to adjust the final size of the network is by changing the cognitive parameters in ACT-R, for instance adjusting memory decay speed or base level learning activation. Moreover, our results also imply, at least for our world, that navigation strategies and environmental complexity do not significantly influence the number of friends that a person can maintain in memory (Dunbar’s number), as the average number of relations were same for both networks. They do, however, suggest the ecological factors significantly contribute to the degree of localization, and perhaps in a more complex world the total size and evolution of the network as defined by the number of total environmental possibilities.

## Future Work

Future work will build upon both our insights regarding the effect of cognitive resources on network topology, as well as rate of growth. First, we would like to extend our analysis of the normalized thresholds to see if there are regularities in their effects on network topology. Second, we will run more agents, because our test systems were kept deliberately small. Finally, we will extend our analysis on the effects of cognition on network measures analogous to Dunbar’s Number, such as information and knowledge diffusion.

## Abstract

Face recognition is an important area of research in cognitive science and machine learning. This is the first paper utilizing deep learning techniques to model human's attention for face recognition. In our attention model based on bilinear deep belief network (DBDN), the discriminant information is maximized in a frame of simulating the human visual cortex and human's perception. Comparative experiments demonstrate that from recognition accuracy our deep learning model outperforms both representative benchmark models and existing bio-inspired models. Furthermore, our model is able to automatically abstract and emphasize the important facial features and patterns which are consistent with the human's attention map.

**Keywords:** face recognition; attention model; deep learning.

## Introduction

Face recognition plays an important role in the social life and attracts interest from a very broad range of researchers and scientists (Anderson, 1998). In machine learning and computer vision areas, face recognition using computational models is a classical problem. The representative models include: Eigenface (Turk, et al., 1991), Fisherfaces (Belhumer, et al., 1997), support vector machine (SVM) (Müller, et al., 2001), and so on.

In cognitive science, face recognition is a vividly researched area (Gauthier, et al., 2000) (Afraz, et al., 2006) (Civile, et al. 2011). It is argued that face perception is involved in a unique cognitive process compared with non-face object or scene perception. Researchers in cognitive science seek to understand how the visual system transforms a face image from an initial, pixel-like representation, to a new powerful form of representation, and finally induce the selectively response of the neurons in inferior temporal cortex (Afraz, et al., 2006). Hence, the researchers have utilized some signal processing techniques to simulate the response of human visual system, such as human's attention allocation. Computational attention model is utilized to measure of the conspicuity and provide the predictions about which regions are likely to attract observers' attention (Koch et al., 1985) (Parkhurst et al., 2002). Many empirical

validations have demonstrated that attention models have notable ability in various tasks, such as content aware resizing (Avidan et al., 2007), quality assessment (Zhong et al., 2010), and face recognition (Cappelli, et al., 2007) (Fang, et al., 2011).

This paper models human's attention for face recognition via deep learning technique. Deep learning models the learning tasks using deep architectures composed of multiple layers of parameterized nonlinear modules. Deep model is selected in this paper because of two considerations. First, the multiple layers deep architecture is consistent with the laminar structure of human's brain cortex and the information delivery in deep model simulates human's visual cortex. Second, deep learning has demonstrated distinguished ability of information abstraction and robust performance of data classification in various visual data analysis tasks (Hinton, et al., 2006).

This is the first paper utilizing deep learning techniques to model human's attention for face recognition. Compared with existing face recognition models, our proposed bilinear deep belief network (BDBN) has several attractive characters:

- 1) BDBN maximizes the discriminant information in a frame of simulating the human visual cortex and human's perception. As we known, nearly all existing machine learning models aims to find the discriminant solution to face recognition applications. Existing computational cognitive model emphasizes the identity between the model and the human visual system. Our model attempts to integrate the advantages of both techniques and provide a new thought of this problem.
- 2) Compared with existing computational face recognition models or representative attention models, BDBN has the ability to automatically extract and emphasize the important facial features and patterns which are consistent with the human attention map.
- 3) BDBN includes three learning stages: semiconducting bilinear discriminant initialization, greedy layer-wise reconstruction, and global fine-tuning. The rational of

three-stage learning comes from the phenomenon of two peaks activation in visual cortex areas. With regard to object recognition, the early peak is related to the activation of an “initial guess” based on the acquired discriminative knowledge, while the late peak reflects the post-recognition activation of conceptual knowledge related to the recognized object.

### Model

In this section, we design a deep learning algorithm with a deep architecture for the task of face recognition, includes bilinear discriminant initialization, greedy layer-wise reconstruction and global fine-tuning. The strategy of bilinear discriminant projection is utilized to construct a projection to map the original data into a discriminant preserving subspace. And it determines the initial parameters and sizes of the upper layer. To human, this strategy is consistent with the early peak related to the activation of “initial guess”. In the stage of greedy layer-wise reconstruction, the parameter space is refined by the greedy layer-wise information reconstruction using Restricted Boltzmann Machines (RBMs) (Smolensky, 1986) as building blocks. In the stage of global fine-tuning, we refine the parameter space for better face recognition performance. And it is consistent with the late peak related to the activation of “post-recognition”. After the deep learning model is constructed, the attention map is built based on the parameter space in the first RBM.

Figure 1: Architecture of the bilinear deep belief network.

Figure 1 shows the architecture of our bilinear deep belief network. A fully interconnected directed belief network

includes input layer  $H^1$ , hidden layer  $H^2, \dots, H^N$ , and one label layer  $La$  at the top. The input layer  $H^1$  has  $I \times J$  units, and this size is equal to the dimension of the input features. In our model, we use the pixel values of sample datum  $\mathbf{X}_k$  as the original input features. In the top, the label layer has  $C$  units, which is equal to the number of classes. The search of the mapping function from  $X$  to  $Y$  is transformed to the problem of finding the optimum parameter space  $\theta^*$  for the deep architecture.

In our deep learning architecture,  $X$  is a set of data samples,  $X = [\mathbf{X}_1, \mathbf{X}_2, \dots, \mathbf{X}_k, \dots, \mathbf{X}_K]$ .  $\mathbf{X}_k$  is a sample datum in the image space  $\mathbb{R}^{I \times J}$  and  $K$  is the number of sample data.  $Y$  is a set of labels corresponding to  $X$ ,  $Y = [\mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_k, \dots, \mathbf{y}_K]$ .  $\mathbf{y}_k$  is the label vector of  $\mathbf{X}_k$  in  $\mathbb{R}^C$ ,  $y_k^c = \begin{cases} 1 & \text{if } \mathbf{X}_k \in c\text{th class} \\ 0 & \text{if } \mathbf{X}_k \notin c\text{th class} \end{cases}$ , where  $C$  is the number of classes.

Based on the given training set, the aim in face recognition is to learn a mapping function from the image set  $X$  to the label set  $Y$ , and then recognize the new coming face images according to the learned mapping function.

### Bilinear Discriminant Initialization

In order to preserve the discriminant information in the learning procedure, the objective function of bilinear discriminant initialization could be represented as follows:

$$\arg \max_{\mathbf{U}, \mathbf{V}} J(\mathbf{U}, \mathbf{V}) = \sum_{s,t=1}^K \|\mathbf{U}^T (\mathbf{X}_s - \mathbf{X}_t) \mathbf{V}\|^2 (\alpha \mathbf{B}_{st} - (1-\alpha) \mathbf{W}_{st}) \quad (1)$$

$$s.t. \mathbf{U}^T \mathbf{U} = \mathbf{I}_p, \mathbf{V}^T \mathbf{V} = \mathbf{I}_q$$

where balance weight  $\alpha \in [0,1]$  is the parameter used to balance the between-class weights  $\mathbf{B}_{st}$  and the within class weights  $\mathbf{W}_{st}$ , which are defined as follows (Yan, et al., 2007) (Sugiyama, 2007).

By simultaneously maximizing the distances between data points from different classes and minimizing the distances between data points from the same class, the discriminant information is preserved to the greatest extent in the projected feature space. Solving  $\mathbf{U}$  (or  $\mathbf{V}$ ) with fixed  $\mathbf{V}$  (or  $\mathbf{U}$ ) is a convex optimization problem. Let  $\mathbf{E}_{st} = \alpha \mathbf{B}_{st} - (1-\alpha) \mathbf{W}_{st}$ , with the fixed  $\mathbf{V}$ . The optimal  $\mathbf{U}$  is composed of the first  $P$  eigenvectors of the following eigendecomposition problem:

$$\mathbf{D}_v \mathbf{u} = \lambda \mathbf{u} \quad (2)$$

where  $\mathbf{D}_v = \sum_{st} \mathbf{E}_{st} (\mathbf{X}_s - \mathbf{X}_t) \mathbf{V} \mathbf{V}^T (\mathbf{X}_s - \mathbf{X}_t)^T$ . Similarly, with the fixed  $\mathbf{U}$ , the optimal  $\mathbf{V}$  is composed of the first  $Q$  eigenvectors of the following eigendecomposition problem:

$$\mathbf{D}_u \mathbf{v} = \lambda \mathbf{v} \quad (3)$$

where  $\mathbf{D}_u = \sum_{st} \mathbf{E}_{st} (\mathbf{X}_s - \mathbf{X}_t)^T \mathbf{U} \mathbf{U}^T (\mathbf{X}_s - \mathbf{X}_t)$ .

The above steps monotonically increase  $J(\mathbf{U}, \mathbf{V})$  and since the function is upper bounded, it will converge to a critical point with transformation matrices  $\mathbf{U}, \mathbf{V}$ .

By bilinear discriminant initialization, we obtain the discriminant initial connections in layer pair and utilize the optimal dimension to define the structure of the next layer.

$$A_{ij,pq}^n(0) = (\mathbf{U}_{ip}^n)^T \mathbf{V}_{jq}^n \quad (4)$$

$$P^{n+1} = \text{row}(\mathbf{U}^n), \quad Q^{n+1} = \text{column}(\mathbf{V}^n) \quad (5)$$

### Greedy Layer-Wise Reconstruction

In this section, we describe how to construct the first RBM between the input layer  $H^1$  and the first hidden layer  $H^2$ .

The energy of the state  $(\mathbf{h}^1, \mathbf{h}^2)$  in the first RBM is:

$$E(\mathbf{h}^1, \mathbf{h}^2; \theta^1) = -(\mathbf{h}^1 \mathbf{A}^1 \mathbf{h}^2 + \mathbf{b}^1 \mathbf{h}^1 + \mathbf{c}^1 \mathbf{h}^2) \quad (6)$$

where  $\theta^1 = (\mathbf{A}^1, \mathbf{b}^1, \mathbf{c}^1)$  are the model parameters between the input layer  $H^1$  and first hidden layer  $H^2$ . Therefore, the log-likelihood probability of the model assigned to  $\mathbf{h}^1$  in  $H^1$  is:

$$\log P(\mathbf{h}^1) = \log \sum_{\mathbf{h}^2} e^{-E(\mathbf{h}^1, \mathbf{h}^2; \theta^1)} - \log \sum_{\mathbf{h}^1} \sum_{\mathbf{h}^2} e^{-E(\mathbf{h}^1, \mathbf{h}^2; \theta^1)} \quad (7)$$

By calculating the derivative of Equation (8), we could update the parameter space with respect to the parameter  $\theta^1 = (\mathbf{A}^1, \mathbf{b}^1, \mathbf{c}^1)$ .

$$\begin{aligned} \frac{\partial \log p(\mathbf{h}^1(0))}{\partial \theta^1} &= - \sum_{\mathbf{h}^2(0)} p(\mathbf{h}^2(0) | \mathbf{h}^1(0)) \frac{\partial E(\mathbf{h}^2(0), \mathbf{h}^1(0))}{\partial \theta^1} + \\ &\sum_{\mathbf{h}^2(t)} \sum_{\mathbf{h}^1(t)} p(\mathbf{h}^2(t), \mathbf{h}^1(t)) \frac{\partial E(\mathbf{h}^2(t), \mathbf{h}^1(t))}{\partial \theta^1} \end{aligned} \quad (8)$$

The above discussion is the greedy layer-wise abstraction for the first layer  $H^1$  with its next adjacent layer  $H^2$ . Similar operations can be performed on the higher layer pairs.

### Global Fine-Tuning

In this section, we use backpropagation to adjust the entire deep network to find good local optimum parameters  $\theta = [\mathbf{A}, \mathbf{b}, \mathbf{c}]$  by minimizing the recognition error  $[-\sum_i \mathbf{y}_i \log \hat{\mathbf{y}}_i]$ , where  $\mathbf{y}_i$  and  $\hat{\mathbf{y}}_i$  are the correct recognition label and the output recognition label value of labeled sample datum  $\mathbf{X}_i$  in  $X^L$ .

Above, we utilize the greedy layer-by-layer algorithm to learn a deep model with the help of discriminant information obtained from bilinear discriminant projection. Therefore, the convergence in our algorithm obtained from backpropagation is not slow. And the result generally converges to a good local minimum on the error surface.

### Attention Modeling

The weights of first layer of BDBN are oriented, Gabor-like and resemble the receptive fields of V1 simple cell (Zhong, et al., 2011). Therefore, the first RBM is utilized to construct the attention model which is shown in Figure 2.

To every neuron in the input layer, the weight value to the one in the first hidden layer is calculated as feature map. Then, the weight value of every neuron is normalized and combined into an attention map.

Figure 2: Construct attention model by first RBM in bilinear deep belief network.

## Experiment 1: Recognition Accuracy Analysis

### Dataset

The CMU PIE face dataset collected between October and December 2000 contains 68 subjects with a total of 41,368 face images (Sim, et al., 2002). The face images were captured by 13 synchronized cameras and 21 flashes, under varying pose, illumination and expression. In the first experiment, we use all the images under different illuminations and expressions with five near frontal poses (C05, C07, C09, C27, C29). Thus we obtain 170 images for each individual.

### Procedure

For the CMU PIE face dataset, the preprocessing is applied following the general setting of experiment (He, et al., 2005). Original images are normalized (in scale and orientation) so that the two eyes are aligned at the same position. Then, the facial areas are cropped into the final images for matching. The size of each cropped image in all of the experiments is  $32 \times 32$  pixels. Sample images after preprocessing are shown in Figure 3.

Figure 3: Sample images after preprocessing from CMU PIE.

In our experiments, the balance weight of our model is set as 0.5 for simplicity. For parameters such as the learning rate and the momentum, we simply follow the general setting of previous work on computational deep networks (Bengio, et al., 2006), although more careful choice may lead to better performance. In the fine-tuning stage, the method of conjugate gradients is utilized and three line searches are performed in each epoch until convergence.

To adapt the real-world face recognition tasks, our computational neuroscience model BDBN is applied under a semi-supervised learning framework. It makes face recognition work well when labeled images are insufficient. 120 images are randomly selected for each person to form the training set and the rest to form the test set. Of the 120 images for each person, different numbers of images are randomly selected and labeled while the others remain unlabeled. The number of labeled data per subject is equal to 5, 10, 20 and 40, respectively. We perform 10 random splits and report the average results over the 10 trials.

## Experimental Results

In the first experiment, we compare three representative face recognition models, including: Eigenface (Turk, et al., 1991), Fisherfaces (Belhumer, et al., 1997), SVM (Müller, et al., 2001), and existing bio-inspired Sparse Localized Features (SLF) model (Mutch and Lowe, 2008).

SVM, Eigenface, and Fisherfaces both are representative benchmark machine learning models for the task of face recognition. The bio-inspired Sparse Localized Features (SLF) (Mutch and Lowe, 2008) are an extensions of the C2 features from the Serre et al. HMAX model (Serre, et al., 2007). For this representation, we took advantage of the MATLAB code provided by the authors. Here, the SVM classification was based on a linear kernel with normalized training and testing data (zero-mean and unit-variance feature-wise).

The recognition accuracy rate with different numbers of labeled data is shown in Table 1. As shown in Table 1, the recognition accuracy rate of bio-inspired models SLF+SVM and BDBN is better than machine learning models Eigenfaces and SVM. And our proposed BDBN has the best performance than others.

Table 1: Recognition accuracy rate (%) on the test data with different numbers of labeled data per category on CMU PIE.

Num./Cat.	20	30	40	50
Eigenfaces	61.9 $\pm$ 0.7	72.1 $\pm$ 0.6	78.2 $\pm$ 0.5	83.8 $\pm$ 0.4
Fisherfaces	84.5 $\pm$ 0.7	92.0 $\pm$ 0.6	93.1 $\pm$ 0.5	94.8 $\pm$ 0.3
SVM	73.5 $\pm$ 0.6	80.4 $\pm$ 0.5	82.9 $\pm$ 0.5	87.1 $\pm$ 0.3
SLF+SVM	80.5 $\pm$ 0.6	86.8 $\pm$ 0.5	89.5 $\pm$ 0.5	90.2 $\pm$ 0.3
Semi_DBN	85.4 $\pm$ 0.7	92.4 $\pm$ 0.6	93.5 $\pm$ 0.5	95.0 $\pm$ 0.3
BDBN	88.4 $\pm$ 0.7	93.9 $\pm$ 0.6	94.3 $\pm$ 0.5	96.6 $\pm$ 0.3

## Experiment 2: Face Feature Points Emphasis

### Dataset

The BioID face dataset consists of 1521 gray level images collected contains 23 subjects (HumanScan, 2003). The face images in BioID are under a large variety of illumination, background.

In this dataset, the x and the y coordinate of the left eye and the right eye are provided. Furthermore, the 20 important facial feature points are manually placed, including: right eye pupil, left eye pupil, right mouth corner, left mouth corner, outer end of right eye brow, inner end of right eye brow, inner end of left eye brow, outer end of left eye brow, right temple, outer corner of right eye, inner corner of right eye, inner corner of left eye, outer corner of left eye, left temple, tip of nose, right nostril, left nostril, centre point on outer edge of upper lip, centre point on outer edge of lower lip, and tip of chin. These facial feature points are thought to be very useful for facial analysis and gesture recognition (Jesorsky, et al., 2001) (Wang, et al., 2002) (Cappelli, et al., 2007).

### Procedure

As a deep learning model for face recognition, BDBN has demonstrated the impressive recognition performance in this first experiment. In this experiment, we intend to investigate the consistency between the emphasized regions in BDBN and the attention map of human being.

The number of images in every category of BioID is varied, from 35 to 118. Therefore, firstly, we choose the categories with more than 50 face images as the subset we work on. Then, just like the procedure on face datasets, the original images are normalized (in scale and orientation) so that the two eyes are aligned at the same position. Finally, the facial areas are cropped and downsampled into the final images. The size of each final image in all of the experiments is 32 $\times$ 32 pixels, with 256 gray levels per pixel. Some sample images after preprocessing are shown in Figure 4.

Figure 4: Sample images after preprocessing from BioID.

Then, to every image in BioID face dataset, we directly input the original pixel value to the BDBN model. After

bilinear discriminant initialization and layer wise reconstruction, we evaluate the consistency between the constructed attention model and human's attention map.

## Experimental Results

Computational attention model was called saliency map first appeared in (Koch, et al., 1985). Typically, multiple low-level visual features such as intensity, color, orientation, texture and motion are extracted at multiple scales. After a feature map is computed for each of the features, they are normalized and combined into a master saliency map that represents the saliency of each pixel.

To face images, some facial areas are assessed to be attracted more attention and helpful to face recognition, for example eye, ear, nose and mouth (Hickman, et al., 2010). Fortunately, in this dataset, 20 important facial feature points are manually selected out and placed. Therefore, with marked facial feature points, the attention model based on deep learning model could be evaluated without eye tracking recordings.

Different from representative attention map which utilizes various features such as intensity, color, orientation, only the gray level pixel values are input into our model. Our attention model automatically extracts and emphasizes important features and patterns to construct facial attention model.

To demonstrate the effectiveness of our model, firstly, the visualization of the parameter space of proposed model is observed. Figure 5 (a) shows a sample image, and Figure 5 (b) shows the sample image with the facial feature points. Figure 5 (c) visualizes the parameter spaces between the input layers and the first hidden layer in BDBN. Each picture shown below represents one neuron in the hidden layer and each pixel quantizes the weight value between that neuron and the one in the input layer. Obviously, the proposed BDBN can automatically extract and emphasize the important areas of human's face, such as the eyes, eyebrows, noses, cheeks, mouths and chins.

Then, we construct the saliency regions based on the emphasized regions of BDBN. Just like the Figure 5 (c), the weight value between each neuron in the input layer to the one in the first hidden layer is calculated at first. Then, the weight value of every neuron is normalized and combined into a saliency map. According to the x and the y coordinates of the 20 important facial feature points of every face image in the dataset, we statistically analyze the percentage of all facial feature points located in the saliency regions of the saliency map.

There are 63.71% facial feature points are located inside 30% most saliency regions and only about 1% facial feature points are located outside 80% most saliency regions. It is obviously that proposed BDBN covers most of important facial feature points. From Figure 4, some of other information and regions are useful to recognize people, such as the hairstyles and the face contour, although they are not belong to the 20 important facial feature points. And as shown in Figure 5 (c), these information and regions are

also emphasized in the parameter space of proposed model. Therefore, if the importance from other important regions for face recognition is excluded, the facial feature points cover percentage in saliency map will be much better.

In Figure 6, the comparison of different computational attention maps are provided, including Graph Gabor attention map (Harel, et al., 2006), Itti classical attention map (Itti & Koch, 2000) and BDBN attention map. It is obviously that BDBN has better coverage than other models. It proves that BDBN provides a human-like judgment by referencing the human visual system.

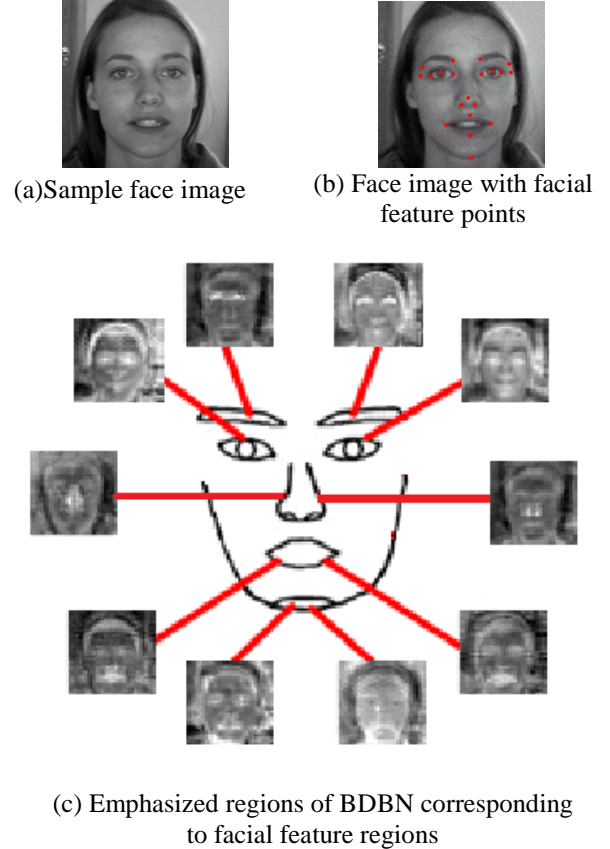

Figure 5: Samples of first layer weights learned by BDBN, and the consistency of these weights with facial feature points.

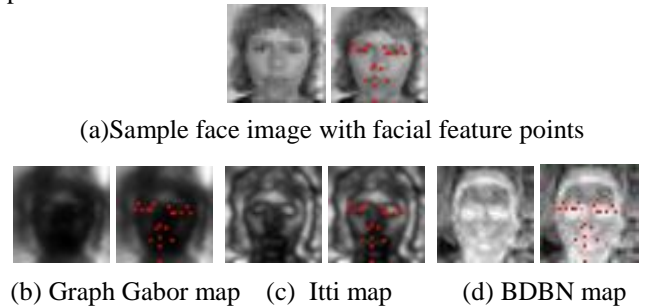

Figure 6: The comparison of different attention maps with facial feature points.

## Conclusion and Future Work

In this paper, we make an attempt to construct an attention model for face recognition in a frame of simulating the human visual cortex and human's perception. To evaluate proposed face recognition models, we do experiments on two face images' datasets, CMU PIE and BioID. Experiments results not only show the distinguishing recognition ability of our deep model but also clearly demonstrate our intention of providing a human-like face image analysis by referencing the human visual cortex and perception procedure.

It is the general opinion that advances in cognitive science especially neuroscience will provide useful insights to computer scientists into how computer models construct, and vice versa. To a certain extent our attempt is an example to prove that the computational models are not only applied into the tasks of classification and recognition just as the optimal classifier, they also can provide human-like response by referencing the human visual system. In future, we will go on this direction to propose novel computational model by referring more characters of human visual system. And vice versa, in cognitive science, we will explore whether the human visual system possess the related mechanism which is consistent with the computational model from the viewpoint of mathematics.

## Abstract

The work presented in this paper has been carried out in the context of a summary writing environment provided with automatic grading. Regarding summarisation discourse, some of the most relevant variables identified in previous work are comprehension, adequacy, use of language, coherence, and cohesion. This work is focused on cohesion. The described exploratory study starts from basic automatic measures of cohesion to further analyse which of them best reflects human expert overall cohesion grades for learner summaries written in the Basque language. For this purpose, 45 basic cohesion measures are compared to overall human cohesion grades. Machine Learning techniques are used to select the best combination for cohesion grading.

**Keywords:** Cohesion grading, machine learning, automatic scoring.

## Introduction

A summary is a short clear description that provides the main facts or ideas about a given topic. In educational contexts, a summary is an overview of the most important information on the studied theme. Summarising requires active meaning construction to a much greater degree than choosing a response in a multiple-choice test, or even than writing short answers to isolated open questions. Thus, not only is summary writing an effective means to construct and integrate new knowledge, it is also a more efficient method for assessing what students do and do not understand than traditional comprehension tests (E. Kintsch, Steinhart, Stahl, & the LSA Research Group, 2000). Thus, summaries are widely used in traditional teaching as an educational diagnostic strategy to infer comprehension, or how much information from the reading text is retained in memory (Bartlett, 1932; Garner, 1982; W. Kintsch, Patel, & Ericsson, 1999).

However, evaluating and grading summaries is a complex and time consuming task for teachers. Human judges have certain variance on summary grading. So, there is a need to systematise written summary evaluation for students. Researchers have sought to develop applications that automate summary grading and evaluation in a way that a given summary will always gain the same score.

Most of the work carried out in Computer Assisted Assessment has tried to infer the student's knowledge comprehension by analysing and comparing the answer generated by the student either explicitly represented in the system –mostly multiple choice questions– or with answers that

could be obtained using the knowledge represented in the system. The automatic evaluation of open-ended text, e.g. summaries, is a complex task strongly conditioned by text comprehension methods; statistical modelling, and Natural Language Processing (NLP) techniques. The open-ended assessment mode, although less accurate than the close-ended mode, has been present in Artificial Intelligence and Education since the very early work in Socratic dialogues systems (Clancey, 1982; Ford, 1988; Woolf, 1988; Winkels & Breuker, 1989). After these first works, there was a period when open-ended approaches had a lower profile, but new developments in NLP and cognitive modelling have seen a revival with a variety of approaches in various applications: dialogue systems (Schulze et al., 2000; A. Graesser, Person, & Harter, 2001; Zinn, Moore, & Core, 2002), feedback on narratives (Robertson & Wiemer-Hastings, 2002), and so on.

The work presented in this paper has been carried out in the context of a learner oriented summary writing environment provided with automatic grading, LEA (Zipitria, Arruarte, & Elorriaga, 2008b). Relevant variables identified when producing a summarisation environment are: text related (text type, text present/absent, theme and text length), discourse related (comprehension, adequacy, use of language, coherence, and cohesion), learner related (learner level and learner's prior knowledge) and available aid tools (dictionaries, spell and grammar check, theory in summarisation strategies, concept maps, schema, etc.). Those variables have been identified after an in-depth study of both the state of the art in summary grading and an empirical study carried out to observe human summary grading performance to model their criteria (Zipitria, Larrañaga, Armañanzas, Arruarte, & Elorriaga, 2008a).

In the context of this work, the global summary grading decisions are gained by means of a Bayesian Network based modelling approach, based on measures such as: comprehension, adequacy, use of language, coherence, and cohesion (Zipitria et al., 2008b).

- **Comprehension.** Comprehension measures the level of understanding that can be inferred from each summary.
- **Adequacy.** It refers to the use of adequate register and terminology in the written summary.
- **Use of language.** It looks at orthographic, syntactic and lexical errors (Cassany, 1993).

- Cohesion and coherence. Coherence and cohesion are closely related and often used as synonyms. A way of distinguishing both concepts is suggested by A. C. Graesser, McNamara, Lowerse, and Zhiqiang (2004), who refer to coherence as a psychological construct, whereas cohesion is referred to as a textual construct. Similarly, Todd, Khongput, and Darasawang (2007) in a connective cohesion study say that cohesion refers to explicit connective links, whereas coherence refers to implicit connections. Therefore, coherence would exist in the way that people interpret text rather than in the texts themselves, while cohesion would be provided by the text features. Cohesion has been defined by Halliday and Hasan (1976) as a set of resources for constructing relationships in discourse transcending grammatical structure (reference, ellipsis, substitution, conjunction, lexical cohesion, etc.). Hence, the aim of cohesive studies is to measure the way text discourse is tied in language. Cohesion features have been measured in this study to resemble human global cohesion grades.

In LEA, comprehension and coherence are modelled based on Latent Semantic Analysis (Zipitria, Arruarte, & Elorriaga, 2006) and adequacy and use of language are computed based on surface measures gathered from tagged text and statistical analysis. The present study describes the procedure followed searching for the best available approach to model overall cohesion grading of learner summaries written in Basque language<sup>1</sup>.

The paper is organised as follows. Section 1 is a summary of previous work that includes measures of cohesion and Section 2 describes the cohesion grading experimental setting, results and discussion.

### Previous work measuring cohesion

Cohesion has already been automatically measured under different approaches and for a variety of purposes.

Morris and Hirst (1991), in a domain independent approach, analyse lexical cohesion in text. Lexical cohesion is measured as a result of chains of related words that contribute to the continuity of lexical meaning. These lexical chains are a direct result of units on the same topic. A thesaurus is used as the knowledge base for computing lexical chains. Lexical chains are also used to determine text structure. E. Kintsch et al. (2000) took an LSA approach to cohesion, gaining sentence to sentence paraphrasing measures for learner summary grading purposes. Alonso and Fuentes (2003) describe the integration of cohesive properties with coherence for automatic summarisation purposes. An account for cohesive formation is gained by means of diagnosis of lexical cohesive chains as extra-strong, strong and medium-strong. A. C. Graesser et al. (2004) present a wide account in cohesion and coherence measures, producing over 200 measures –over 50 types

<sup>1</sup>Non Indo-European language spoken in the north of Spain and south of France. Grammatically complex, it is an agglutinative, order free and verb final language. A complete English description of the Basque grammar can be found in Hualde and Ortiz de Urbina (Hualde & Ortiz de Urbina, 2003).

of cohesion– based on surface linguistic features in a tool called Coh-Metrix. Siddharthan (2006) refers to work in automatic text production that applies a syntactic simplification process as a way to reduce comprehension complexity and maintain cohesiveness. Adequate sentence ordering, cue word selection, referring expression generation, determiner choice and pronominal use are resolved to preserve cohesiveness. Carenini, Ng, and Zhou (2008) work in the context of automatic summarisation of e-mail conversations. Cohesive measures are collected in the form of clue words or word co-occurrences between adjacent fragments, semantic similarity or subsequent sentence similarity measures based on WordNet and cosine – using TF(Term Frequency) and IDF (Inverse Document Frequency), local and global weights respectively – or segment to segment cosine similarity. Finally, Vechtomova and Karamuftuoglu (2008) measure lexical cohesion between query terms in the context of IR (Information Retrieval) term proximity. Both short distance and long distance collocation relations are measured.

### Cohesion grading experiment

As part of the modelling process to obtain global grades for each summary, the summary grading decision making model (Zipitria et al., 2008b) requires global cohesion grades. The goal of this study is to obtain a model which shows which combination of specific cohesion measures best predict cohesion. In other words, which cohesion features predict the decision of global cohesion of graders in comparison to a real-life cohesion grading task. Human cohesion grades are predicted by automatic measures of discourse cohesive features.

### Procedure

17 human experts were asked to grade the level of cohesion of summaries that had previously been gathered from university students, second language learners and primary and secondary school pupils. Experts were university lecturers or primary and secondary and L2 teachers who had been teaching summarisation strategies for more than a decade. A total of 17 summaries were written in Basque language. The goal was to obtain a wide range of different scenarios involving cohesion in summarisation. Grades were gathered on a 1 to 10. Each of the 17 raters produced grades for every summary with a between-rater agreement  $r = 0.7$  and  $p < 0.05$ . Finally, all the grades were discretized into *Fail*, *Pass* and *Distinction*.

The task for expert grading participants consisted of reading the text based on which the summaries were written. Next, they were expected to read each summary to produce global cohesion grades. In order to avoid misconception, verbal and written definitions on cohesion were provided to experts.

In parallel, cohesion measures were automatically modelled using NLP techniques. The mean scores of the graders were compared to cohesion measures in order to observe the amount of information explained by the cohesion measures.

**Cohesion measures (X)** Cohesion measures were created (see Table 1) based on theory on English discourse cohesion (Halliday & Hasan, 1976; Schiffrin, Tannen, & Hamilton, 2001) and language specific differences for Basque (Hualde & Ortiz de Urbina, 2003). In addition, previous modelling work has also been taken into account (Baayen, 2001; A. C. Graesser et al., 2004). 45 markers aiming to word variability, text structure, lexical cohesion, conjunctions and verbal cohesion have been studied:

#### *Word variability*

A total of 14 measures which refer to vocabulary variability related information: X1 Size of the sample in word tokens, X2 Number of distinct lemmas, X3 Number of distinct word tokens, X4 Distinct concept proportion in text, X5 Concept proportion among word variability, X6 Mean number of letters per word, X11 Measures on how single word measures deviate from the central word mean tendency, X12 Mean of word tokens to number of distinct word types, X13 Word proportion in text and X14 Lemma proportion in text.

#### *Text Structure*

This refers to the cohesion which is inherent to the textual structure as narrative, formal correspondence, sonnet, etc. (Halliday & Hasan, 1976). Four surface structure measures have been measured to reflect structure: X7 Mean sentences per paragraph, X8 Number of paragraphs, X9 Number of sentences and X10 Average words per sentence.

#### *Lexical cohesion*

In lexical cohesion the same word is repeated and has the same referent in both cases. It is not necessary for the second instance to be an exact repetition of the same word (Halliday & Hasan, 1976).

Two measures emulate lexical cohesion indices measured by means of overlapping concepts in subsequent sentences. Overlapping concepts are measured as word overlap and lemma overlap: X15 Cosine of overlapping words in subsequent sentence comparison and X16 Cosine of overlapping lemmas in subsequent sentence comparison.

#### *Conjunction and connectors*

Conjunctive elements are cohesive by means of their specific meaning. They express meaning which presuppose the presence of other components in discourse. It is based on the assumption that there are forms of systematic relationships between sentences (Halliday & Hasan, 1976). 16 indices have been measured with the aim of capturing the cohesion provided by conjunctive relations: X17 Average commas per sentence, X18 Measures on how single comma measures deviate from the central word mean tendency per sentence, X19 A rule based approach to the adequate use of the comma, X20 Amount of commas, X21 Number of connectives, X22 Number of additives, X23 Additive type-token ratio, X24 Number of quantifiers, X25 Connector type-token ratio, X26 Number of adversatives, X27 Adversative type-token ratio, X28 Number of distributive connectors, X29 Distributive tokens between connective tokens, X30 Connective tokens between word tokens, X31 Number of types of connectors and X32 Connective tokens times connector variety.

#### *Verbal cohesion*

Verbal forms in Basque provide important ties in discourse cohesion. Verbs can consist of single words (synthetic) or consist of a participial form and an auxiliary (analytical). Auxiliaries can also be used as the main verb. Participles carry aspectual information whereas auxiliaries convey information about argument, structure, tense and mood. Auxiliaries vary in four different tenses/aspects: present, past, hypothetical and imperative (Hualde & Ortiz de Urbina, 2003). Ties provided by verbal forms are measured by a total of 13 indices: X33 Average number of words before verb, X34 Measures on how single measures of word occurrences before verb deviate from the central tendency, X35, verbs per sentence, X36 verbs per sentence by verb variability, X37 Number of Verbs, X38 Number of distinct Verbs, X39 Verb type/token ratio, X40 Number of Transitive Verbs, X41 Number of distinct Transitive Verbs, X42 Transitive Verb type-token ratio, X43 Number of auxiliary verbs, X44 Distinct auxiliary verbs and X45 Auxiliary verb type/token.

The process from text to cohesion measure implementation starts with: (1) Text splitting and tagging. Next, (2) Texts are automatically analysed using POS (Part Of Speech) tagging with a morphosyntactic analyser (Aduriz et al., 2004) and a dependency parser (Bengoetxea & Gojenola, 2009). (3) Finally, there is a statistical processing to obtain the cohesion measures.

The human and automatic cohesion grades obtained were discretized to be analysed under several Machine Learning classification strategies.

## **Results**

This Section describes the ML analysis followed in this study.

**Experimental Design** In order to detect relevant cohesion measures (variables), we first describe how a Feature Subset Selection (FSS) can be performed in an automatic way. After applying different FSS approaches, Feature Selection allows to find the relations between the selected cohesion measures (variables) and the global cohesion grade. The relation is measured based on a set of classifiers. Finally, the goodness of the measure is considered based on the obtained grading accuracy.

In addition to the filtered and wrapper variable selections, the classifiers have also been applied to measure the cohesion for the eight most common variables in previous cohesion measures and the combination of all the 45 measures. The next Section, introduces the description of the variable sorting approach taken for this dataset in the filter approach.

It is worth mentioning that all the experiments have been carried out using the Leave One Out validation technique; this implies learning the classifier with all but one example, and then applying the obtained classifier to the example which has been left out. This process is repeated 17 times (once by example) for each classifier and feature set.

Table 1: Cohesion measures' predictive effect sizes

Type	Measure	$f^2$	$R^2$	Sig.
Word variability	X1	.161	.078	.155

	<b>X44</b>	<b>.291</b>	<b>.171</b>	<b>.063</b>
	<b>X45</b>	<b>.322</b>	<b>.19</b>	<b>.05</b>

**Filters** The use of classifiers requires sorting the variables prior to being classified.

In order to perform the experiment and evaluate the adequateness of the new approach, statistical measures have been used to search for the most salient variables for the cohesion problem. The formulas used with this purpose are well-known metrics in Feature Selection and behavioural research methods: *Gain Ratio*, *One Rule*, *Recursive Elimination of Features (RELIEF)*, *Support Vector Machines (SVM)*, *Chi-square ( $\chi^2$ )*, *Principal Component Analysis (PCA)* and *Effect size ( $f^2$ )*. Selected cases are marked in Table 1.

Table 2: Variable ordering obtained for each of the statistical metrics

Metric	$f^2$	GR	OneR	Relief	SVM	$\chi^2$	PCA
First	X4	X15	X35	X44	X41	X15	—
Second	X5	X16	X14	X35	X9	X16	—
Third	X6	X12	X36	X36	X19	X12	—
Forth	X14	X14	X10	X14	X44	X14	—
Fifth	X36	X13	X25	X8	X8	X13	—
Sixth	X43	X20	X5	X9	X23	X20	—
Seventh	X44	X22	X15	X43	X7	X22	—
Eighth	X45	X21	X17	X4	X26	X21	—

**Variable selection based on filtering strategies** Variable sorting under the previously described filtering strategies can

be found in Table 2; it should be noticed that the PCA approach does not give a ranking among the variables, but a set of polynomials with linear combinations of some features, this is the reason why the PCA column in Table 2 is empty.

The ML experimental phase has been organised in the following way: First, each of the five selected classifiers has been used to measure the impact of the cohesion measures for the set of student summary global cohesion grades. As shown in Table 3, the first variable in the ordering given for each metric was taken into account first. Next, a second variable is included for each metric, and the accuracy obtained with these two variables is tested with all the classifiers. The same process is run including the third, fourth, and so on variables until a decrease in the accuracy is obtained. Results in Table 3 show that the variable number for each filter is different depending on the moment when an error increase appears.

Table 3: Number of errors obtained by each approach for each subset of variables. PCA approach does not use individual variables but a linear combination of some of them.

Metric	N	Variables	BN	NB	K-NN	SVM	ANN
6*f2	1	X4	8	12	12	10	8
	2	+X5	8	12	12	10	8

The variable subset with the best results in the filter approach is composed of the first four variables selected with the SVM filtering metric for the K-NN classifier. It shows an accuracy of 4 errors and the combination is compound by the next variables: X41, *transitive verb types*, **verbal cohesion**.

*X9, number of sentences text structure. X19 excessive use of commas connectives. Finally, X44 distinct auxiliary verbs verbal cohesion.* The same combination of variables obtains the best result with the NB paradigm.

Table 4: Number of errors obtained by each approach using the wrapper FSS.

	BN	NB	K-NN	SVM	ANN
Errors	7	5	2	6	4
Variables	X15	X44	X11, X44	X41, X44	X33, X44
ALL	9	9	10	8	12
Experts	9	9	10	5	11

**Variable selection based on wrapper strategies** The variable subset with the best results in the wrapper approach is composed of the first two variables selected with the K-NN classifier. It shows an accuracy of 2 errors and the combination is compound by the next variables: *X11 single word measures deviation from the central word mean tendency* taken from the **Word variability** related variable set, and *X44 distinct auxiliary verbs*, taken from the **verbal cohesion** feature set.

**Variable selection based on some previously used cohesion measures** Previous research (see some examples in Section ) has measured similar factors to account for cohesion. We have selected the next factor combination to observe how they account for cohesion.: *X3 (word types)*, *X6 (mean letters per word)*, *X13 (type-token ratio)*, *X15 (sentence overlap)*, *X21 (number of connectives)*, *X33 (average number of words before verb)*, *X35 (verbs per sentence)* and *X36 (verb variability)*. The combination of the eight previously studied measures (named EXPERT) has been tested under the different classifiers. It should be noticed that in this case the variables are listed using an ascending index. The reason is that the variable ordering is not known. In other words, there is no previous record of one being more relevant than another.

Results are shown in Table 4. The best approximation is provided by the *SVN* variable combination with an accuracy of 5 errors. The results are almost as accurate as the best option based on FSS filter strategies. However, they are still far from the best measures under the wrapper approach and *K-NN*.

**Using ALL the cohesion measures** Another approach is to use all the available indicators to search for cohesion grades. Here, the ALL variable option tests the 45 variables combination for classification purposes.

As shown in Table 4, the ALL variable option does not show accurate results. The accuracy shown is equal to or greater than 8 errors. Again, from the classification paradigms, *SVN* shows the best results.

## Discussion

The goal of this study was to know which measures best predict global cohesion grades. A total of 45 measures were compared to overall cohesion human grades with no previous record on which one was most relevant. The modelling analysis allows searching for the best modelling approach for Basque cohesion grading.

According to the observed results considering all the available information is not the best option for global cohesion grading decision making. The reason for this is redundancy. The EXPERT approach, which combines the most commonly used cohesion measures, has produced a good approximation under SVM classification. Nonetheless, the use of a wrapper approach and K-NN classifier seems to be the best fit for the Basque case.

The difference with the EXPERT combination is probably due to language grammar specific differences. In terms of the variable combination, the amount of auxiliary verb type (*X44*) is the most recurrent one in the best models. This is probably due to Basque grammar morphology. The Basque auxiliary verb carries a lot of grammatical information. Each auxiliary verb provides information about the subject, the two object forms – direct object and indirect object –, as well as tense and aspect. Therefore, the number of auxiliary verb types probably shows how syntactically connected the discourse is. In addition, there are other measures for text structure, word variability, and verbal cohesion which have also been salient.

The obtained model for global cohesion grading will be used as part of a summary evaluation environment (Zipitria et al., 2008a). In order to gain an overall grade for a summary each overall discourse measure is fed into the grading decision making Bayes net (Zipitria et al., 2008b). But, there still are many questions to be answered. Would results be very different if we had measured cohesion indicators that are not included in this study? Does the Basque language require further language specific analysis to better account for cohesion? Would results be very different in another language? Are there interactions among predictors?

We expect that language morphology might be responsible for language differences for cohesion. In future, we aim to analyse the impact that different languages and their morphology make in terms of results. In addition, some of the obtained results might be tied to the particular language under which the study was run. Future work will look at testing the grading scheme under more languages –e.g. Spanish and English– providing LEA with a multilingual approach.

In addition, searching for a greater scope of cohesion measures might also make differences in the results. More theoretically relevant cohesion features (Halliday & Hasan, 1976; Schiffrin et al., 2001) could be automatically modelled and empirically analysed for Basque (e.g. anaphora resolution, ellipsis, etc). A wider collection of measures and further Natural Language Processing tools could allow more in-depth analysis of discourse cohesion and probably a greater accuracy.

## Acknowledgments

# The Effects of an Incubation Period on the Metaphor Creation Process

Keiga Abe

Gifu Shoutoku Gakuen University

**Abstract:** This study examines the effects of an incubation period on the creative thinking-process, particularly on the metaphor creation process. In an experiment, participants were asked to create X like a Y type metaphors on the basis of theme phrases, which contain adjectives and nouns. Participants in the control group were asked to create metaphors immediately after they were given the theme phrase. Participants in the incubation group were asked to generate metaphors after a distracter task. Participants in the wait group were asked to create metaphors after-thinking for three minutes. The results of the experiment revealed that when the theme phrases contained connected but complex words, the incubation group created more metaphors than the other groups. When the theme phrases contained diverse but disjointed words, the wait group created more metaphors than the other groups.

# **Trial Measurement of Implicit Attitude toward Violations in Nursing by the use of Implicit Association Test**

**Abstract:** The implicit attitude toward violations is regarded as a contributing factor in those violations. We applied the Implicit Association Test (IAT) to measure this attitude in nursing. This study examines the IAT's validity and reliability. In experiment 1, we conducted IAT and a scale of attitude toward safety for medical staff (Kamizono, 2000) for 71 students from a university of nursing. Validity was demonstrated from a difference of the reaction time between the blocks of IAT and a significant correlation between IAT score and the score of scale. Reliability was indicated by dispersion between trials. In experiment 2, we conducted the IAT for 51 medical staffs who serve as risk managers in a hospital. The IAT's validity was demonstrated from a difference of the reaction time between the blocks of IAT and reliability was indicated by dispersion between trials, too.

# Frame Augmented Language Model

**Kisuh Ahn**

Hankuk University of Foreign Studies

**Eunsuk Lim**

Hankuk University of Foreign Studies

**Abstract:** N-gram based statistical language model is widely used in NLP applications such as Automated Speech Recognition and Machine Translation due to its ease of use and effectiveness. Given the very simple assumption of this model, the effectiveness of this model is somewhat surprising, but there clearly exist deficiencies such as the inability to account for long-distance dependencies and the lack of considerations for the overall meaning.

There have been various approaches to enhance the n-gram language model by incorporating syntactic and semantic elements. In this paper, we explore the use of frames of the Berkeley FrameNet as a way of augmenting the purely statistically driven language model with semantic information; while the conventional n-gram model supplies the overall probability score of the surface form of a sentence, the candidate frames evoked by this sentence provide the means to calculate the conceptual relatedness among the words within the sentence. The two measures are combined via linear interpolation to give an overall score. In addition to boosting the overall performance, we believe that our approach brings the language model a bit closer to the reality of human language processing.

# **Multi-Voxel Pattern Analysis Applied to the Language Switch in the Bilingual Brain—An fMRI Study**

**Hiroyuki Akama**

Tokyo Institute of Technology

**Miao Mei Lei**

Tokyo Institute of Technology

**Na Li**

Tokyo Institute of Technology

**Brian Murphy**

Carnegie Mellon University

**Abstract:** Previous fMRI studies about bilingual speakers proved that the left caudate and the anterior cingulate cortex (ACC) play the important role in intralanguage task switching (Crinion et al., 2006; Abutalebi et al., 2008). Our research based on Multi-voxel pattern analysis (MVPA) suggests that these brain regions are involved in the language control not only, but also in semantic processing which encapsulates a covert translation between the first/second native languages. Using a set of stimuli which was composed of two semantic categories, Korean-Chinese bilinguals were requested to do a property generation task in Korean for a stimulus word in Chinese, vice versa. Machine learning methods applied to the fMRI datasets enabled us to create, even from the aforementioned regions of interest (relatively small with only about 1000 voxels), significant classification models with the identification accuracy of more than 60% (above chance) for predicting the semantic category of each target.

# Visual prosody: The relationships between head movements and the verbs

Haruka Amatani

University of Tokyo, Meguro-ku, Tokyo, Japan

**Abstract:** Visual prosody consists of head and facial motions which accompany speech prosody. The improvement of speech intelligibility by head movement has been reported by Munhall et al. (2003) and the increase in the perceptual rate of a sentential focus with head or facial movement by Krahmer and Swerts (2007).

Here, I will show that the syntactic structure can influence visual prosody.

With video clips of two Japanese newsreaders from thirty-nine news programs, a perceptual experiment was carried out on untrained twenty-six subjects. They were instructed to judge the timing when the newsreaders made a head nod. It turned out that the speakers had a strong tendency to nod at the matrix verbs. As for the embedded verbs, those in the sentential compliments and in the adverbial phrases frequently co-occur with head nods, whereas those in the relative clauses which modify nouns did much less frequently.

# Determining the effect of ego-involvement on causal reasoning by using contingencies in causal situations

Yoshiko Arai  
Osaka City University

**Abstract:** This study investigates the relation between contingencies and the effect of ego-involvement on causal reasoning in causal situations. In an experiment, participants were informed about their tasks that involved causality, and they were randomly assigned to four conditions: medium contingency without ego-involvement, medium contingency with ego-involvement, high contingency without ego-involvement, and high contingency with ego-involvement. Thereafter, they were asked to rate the strength of the causality of two events. The result showed that the effect of ego-involvement was clear only when the contingency was high: when ego-involvement was present, the causal relationship was judged stronger than when it was absent. This is similar to the result of an experiment in which contingency was considered as a within-subject variable. The result confirmed that ego-involvement affects causal reasoning when the contingency is high.

# Which is Stronger? : Discriminative Learning of Sound Symbolism

**Eiji Aramaki**

The University of Tokyo

**Sachi Yasuda**

The University of Tokyo

**Mai Miyabe**

The University of Tokyo

**Satoshi Miura**

Tottori University

**Masaki Murata**

Tottori University

**Abstract:** Abstract: The importance of sound symbolism of a product name has been emphasized in recent researches. However, detailed mechanisms of sound symbolism remain controversial, even in reports of recent studies. This study examines a method to detect sound symbolism using discriminative learning. First, we build a training dataset comprising name pairs: (1) name-A, (2) name-B, and (3) a label showing which has stronger sound symbolism. Next, we train a Support Vector Machine (SVM) to learn data using both character-based features and phoneme-based features. In experiments, the proposed method demonstrated almost identical performance to that of humans (72% agreement ratio to humans). This paper also presents a method to generate new names with strong sound symbolism based on greedy search. The generated names have high agreement to human judgments (84%). This the first study suggesting that machine learning can detect sound symbolism.

# The model comparison through orthography, phonology, and semantics

**Shin-ichi Asakawa**

Tokyo Woman's Christian University

**Abstract:** We tried to compare the performances of 3 neural network models. Those were perceptrons, back-propagations, and attractor networks. Perceptrons are two-layered model without any hidden layers. On the other hand, back-propagation models are 3-layered models with a hidden layer. In addition to the hidden layer, attractor networks have a cleanup layer from/to the output layer. We had all the models learnt the data sets of Hinton & Schallice(1991), Plaut & Schallice (1993), and Tyler et al(2000). The components of language processings are divided to three parts, orthography, phonology and semantics. The comparison among the models and the data sets revealed adequacy as a model of dyslectic patients. It also revealed that the cleanup layer had to play an important roll in order to process all the data set. The category specificity, which was defined as the inner correlation matrix between concepts, could be simulated, as well.

# Age-related Differences in Implicit Memory for Distractor Kanji Characters

**Akihiro Asano**

Chuo University

**Etsuko T. Harada**

University of Tsukuba

**Shoko Saito**

Chuo University

**Abstract:** Experiments investigating the effects of age and time of testing on implicit memory for distractors were executed with Japanese older and young adults from cross-cultural perspective with a modification of a Rowe, Valderrama, Hasher, and Leanartowicz (2006) procedure. Participants were required to make same or different judgments on line drawings superimposed with irrelevant Kanji characters, and then memory for distractors was tested with a Kanji perceptual identification test. Against expects according to Rowe et al. (2006), and supporting a prior research (Asano, Harada, Suto, Rowe, & Hasher, 2009) used Hiragana words as distractors, results showed that only young adults showed priming for the distractors, without any effects of time of testing. To explain these differences between studies, some hypothesis about cultural or linguistic differences between North Americans and Japanese as East Asians in cognitive processing styles will be discussed.

# **Robots as learning partners in collaborative learning research**

**Jun Ashikaga**

The University of Tokyo

**Takahiro Nakayama**

**Sho Inaba**

The University of Tokyo

**Kenta Iyoki**

The University of Tokyo

**Naomi Miyake**

The University of Tokyo

**Abstract:** Remotely controlled robots can expand our research and practice of collaborative learning. Such robots can be used to run a controlled experiment in classroom-like settings by delivering the same information to different groups, so that we can explore the effects of a particular discourse in collaboration. Using this technique, we have tested 25 groups in jigsaw-like, knowledge-constructive collaborative learning situations, with eighty 5th and 6th graders on science topics. There was one robot for each group, which consisted of 2 to 4 children. We have found that (1) children collaborated well among themselves and (2) they could learn well with such robots. We have also found the groups whose talks focused more on the task performed better than those with less focused talks. Currently we are analyzing the protocols to see what kind of intervention by the robots would have the children focus more on the task.

# What do children hear? Japanese parents' use of numeral classifiers

**Natsuki Atagi**

University of California, Los Angeles

**Catherine Sandhofer**

University of California, Los Angeles

**Abstract:** Previous work on childrens acquisition of Japanese numeral classifiers has provided extensive information regarding classifier acquisition and its effect on cognitive development (e.g., Yamamoto, 2005). However, few studies have examined the considerable variability found in these studies. We propose that variability in childrens classifier acquisition may be due to input. Thus, we examined parent input of Japanese numeral classifiers to Japanese-speaking children. Participants were two- to five-year-old monolingual Japanese and bilingual Japanese-English children and their Japanese-speaking parents. Parents were instructed to read a wordless picture book about counting to their children. Book readings were video-recorded and coded for frequency, type, and correctness of parent classifier use. Children also participated in Give-N and counting tasks. We hypothesize that children whose input includes many generic classifiers (e.g., -ko: generic classifier for inanimate objects) will have more advanced number understanding than children whose input includes more specific classifiers (e.g., -ken: classifier for houses).

# Comparison and contrast in novel objects categorization: the role of executive functions

**Luc Augier**

University of Burgundy

**Jean-Pierre Thibaut**

University of Burgundy

**Abstract:** We investigated how 4- and 6-year-olds use within and between category comparisons when they generalize novel names for novel objects on a nonsalient dimension such as texture (rather than shape). Children first learned a novel name for one or several stimulus. In the generalization phase we pitted a texture match against a shape match and we manipulated the quantity of information (positive or negative evidence). We manipulated number of standards, presence of contrast and age. Our results confirm the role of within category comparisons in texture choices. Further, older children performed significantly better than younger children only when there were four standards. Hence, increasing the load of comparison does not hinder but may be of more help for older than for younger children. We also found a beneficial effect of between category comparisons for both age groups. This is compatible with the role of executive functions in comparisons.

# **Comparison of the brain regions activated during comprehension of action sentences referring to unimanual or bimanual actions: An fMRI study**

**Shunji Awazu**

Jissen Women's University

**Fumihiko Taya**

Keio University

**Sayako Masuda**

Keio University

**Shigeru Watanabe**

Keio University

**Abstract:** Within the framework of embodied cognition, sentences are thought to be comprehended by mental simulations in the sensorimotor system. Several fMRI studies have shown that motor regions are activated during action-sentence comprehension tasks. In this fMRI study, we examined whether all body movements are mentally simulated during these tasks. We assigned action-sentence comprehension tasks to 18 participants for identifying brain regions that are activated while reading sentences referring to unimanual or bimanual actions. When the participants read the bimanual action sentences, left SPL (Brodmann Area 7), IPL (BA40), SFL (BA6) and MCgG (BA23, 24) were activated. Direct comparison between the two conditions found significant activation of left IPL (BA40), IOG and MTG (BA18) in reading the bimanual sentences. Therefore, we conclude that while reading bimanual action sentences, mental simulations occur for bimanual movement as well as for visual experiences. Broad range of brain regions would associate with mental simulations of action sentences.

# Effectiveness of Transcranial Direct Current Stimulation on Medial Prefrontal Cortex in Aesthetic Judgement

**Leila Azari Pishkenari**

Graduate Student at Institute for Cognitive Science Studies, Tehran, Iran, Islamic Republic of

**Hamed Ekhtiari**

Neurocognitive Laboratory, Iranian National Center for Addiction Studies, Tehran, Iran

**Mohammad Javad Hatami**

Head of the MA Program in Cognitive Psychology

**Abstract:** Introduction: Among various brain regions involved in aesthetic judgment, Medial prefrontal cortex has a pivotal role in judging the beauty of visual stimuli. It seems that this regions influence in aesthetic preference is an effect of its role in affective processes. In the following study, we have used transcranial Direct Current Stimulation (tDCS) in order to evaluate the role of medial prefrontal cortex in aesthetic judgment. Method: we used three different types of tDCS stimulation, that is, anodal, cathodal, and sham. 36 participants (18 female) undertook in three experimental sessions randomly in which they received 1mA stimulation for 20 min on their medial prefrontal cortex. Active electrodes were located bilaterally on the forehead and the reference electrode was on the right arm. Ten minutes after the onset of stimulation, subjects got involved in the on-line computerized task of the aesthetic judgment. Results: In general, the effect of tDCS on medial prefrontal cortex on aesthetic judgment was significant  $F(2 \text{ \& } 37.84)=3.89$ ,  $p=0.029$ ). The results show that anodal stimulation of the medial prefrontal cortex affect the aesthetic preference significantly ( $p=0.036$ ), while no such effect was seen in cathodal stimulation ( $p=0.663$ ). There was no sex-related effect ( $F(1 \text{ \& } 33.48)=3.39$ ,  $p=0.074$ ). Discussion: Medial prefrontal cortex through its top-down control over affective side of aesthetic preference can reduce the preference.

# Learning novel words with the help of morphological information

**Sungbong Bae**

Kyungnam University, Korea

**Kwangoh Yi**

Yeungnam University, Korea

**Abstract:** Morphological information can affect the learning rate of new words. To test this hypothesis, we manipulated two variables: individual difference in Morphological Awareness (high vs. low MA groups) and sentential context (consistent vs. inconsistent sentences). 152 college students were asked to learn new words appearing within the contexts of a couple of sentences. The sentential contexts on some trials were semantically consistent with one of the possible morphological structures of words to be learned. The participants with higher MA were better at learning new words despite the definitions of words and morphemes were not given explicitly. Also, the words presented in morphologically consistent contexts were learned faster. More importantly, the effect of context differed among MA groups. The supportive context effect was much bigger for the participants of high MA. In conclusion, this study showed the significant effects of morphological representation and processing in learning new words.

# Distant Border Color Is More Preferred In a Triple Color Combination

**Ziba Bashardanesh**

Institute of Cognitive Science Studies, Iran

**Ali Yoonessi**

School of Advanced Medical Technologies, Tehran University of Medical Sciences, Iran

**Abstract:** Introduction. Previous studies for color preference are mostly limited to choices of one or two color. We used a novel stimulus, a combination of two adjacent squares with a narrow rectangle (border) in between to assess the effect of a third color in the preference for a color combination. We used this method to evaluate the distance of the border color and two peripheral colors in the DKL color space as a predictor for preference. Method. Stimuli consist of all 504 combinations of 9 selected points in the DKL space. On a rectangular representation of DKL with gray in the middle, 9 points were selected including 4 corners, the center and 4 mid-sides. Each possible combination compared with the rest in a forced two choice task in 3024. 50 subjects (25 female and 25 male) in the range of 20-40 years old participated in the experiment. Results. In general, the greater the sum of distances between colors correlated with more preference in the combinations ( $T= 3.585$ ,  $p\text{-value}=0.00$ ). In addition, if the border line settles in longer distance from two other colors, it was preferred more ( $R= -0.726$ ,  $p\text{-value}= 0.00$ ). Conclusion. Distant border color is more preferred in a triple color combination.

# **To peek and to peer: "visual" verb meanings are largely unaffected by congenital blindness**

**Marina Bedny**

MIT

**Jorie Koster-Hale**

MIT

**William Johnston**

MIT

**Lindsay Yazzolino**

MIT

**Rebecca Saxe**

MIT

**Abstract:** Congenitally blind adults learn about the world through touch, audition, and language, but not through vision. What consequences does this atypical sensory experience have for blind adults' concepts of actions and events, especially for features related to vision? One way to assess the structure of concepts is to construct similarity matrices. We elicited similarity judgements for pairs of verbs describing manner of motion (e.g. "to spin", "to strut", n=15), perceptual experience (e.g. "to peek", "to peer", n=60), or perceptible qualities (e.g. "to shimmer", "to shine", n=45). Some of the verbs described qualities or experiences linked to vision. Similarity judgements were acquired from sighted (n=22), late blind (n=9) and congenitally blind (n=24) participants. The similarity ratings for all verb categories, including "visual" verbs, were remarkably similar across groups (all  $r > .85$ ); cluster analyses on similarity ratings produces nearly identical clusters. These results suggest that: 1) verb meanings are largely unaffected by congenital blindness 2) the sensory modality of experience has little effect on conceptual structure.

# Cognitive typology

**Chuluundorj Begz**

University of the Humanities

**Abstract:** This paper presents the dynamic, psycho-cognitive approach to study of human verbal thinking on the basis of typologically different languages /as a Mongolian, English and Russian/. Topological equivalence in verbal communication serves as a basis of Universality of mental structures and therefore deep structures. Mechanism of verbal thinking consisted at the deep level of basic concepts, rules for integration and classification, neural networks of vocabulary. According to the results of psycho-cognitive analysis, semantic bootstrapping serves as a basis of grammatical categories, blending and mental mapping - as a basis for high level linguistic structures (sentence, discourse).

In terms of typologically different languages, topological structure of discourse represents the way in which the individual organizes semantic content, concepts and propositions, in his/her cognitive structure.

Comparative analysis of above named languages has shown that analogical mapping, inference between the properties (like space and time, quantity and quality, shape, color, volume structure) present a basis for semantics transformations. Comparative analysis of the influence of language on cognition proposes a pathway for new developments in psycho-cognitive research, particularly for integral generative semantics in 2D and 3D dimensions.

Key words: verbal thinking, mental structures, blending, mapping, bootstrapping, integral semantics.

# **Expert Memory in Blindfold Chess960 - An Interpretation in the light of LIDA**

**Eduardo Bermudez**

Universidad del Atlantico, Barranquilla, Atlantico, Colombia

**David Dahmen**

Universidad del Atlantico, Barranquilla, Atlantico, Colombia

**Henry Gonzalez**

Universidad del Atlantico, Barranquilla, Atlantico, Colombia

**Abstract:** Chessplayers experts perception is heavily theory laden as evidenced by the performance at recalling chess positions of an expert only allowed to glimpse the board for no more than 10 seconds. When the theoretical background is partially destroyed as in Chess 960, the recall under the same conditions is diminished from about 80% correct recalls to less than 60% (in our experiments). The view that "perception is cognition" seems to have a relation to the concept of sparse dictionaries in the software framework of learning intelligent distribution agent (LIDA). The particular experiments of this paper argue for the former concept and the probable existence of independent networks of activation of memory such as Damasio's zones of convergence-divergence, also compatible with the LIDA concept. Such an interpretation leads not only to reaffirm Ericsson & Kintsch's concept of Long Term Working Memory, but also the hypothesis of a unified theory of memory.

# Vague Linguistic Expressions and the Problem of Equidistance in Verbal Response Scales

**Franziska Bocklisch**

Chemnitz University of Technology

**Josef Krems**

Chemnitz University of Technology

**Abstract:** This contribution examines the problem of equidistance of vague linguistic terms (LT) of verbal response scales, which are used in psychological questionnaires or interviews. The study design (N = 92) employs an empirical translation procedure for the numerical translation of LTs in an example questionnaire (i.e., measuring chronic stress) that utilizes a verbal response scale with frequency expressions (e.g., sometimes). The data are modeled using fuzzy membership functions (MFs) that reflect the LTs meanings. Results show that the LTs of the original questionnaire scale are not distributed equidistantly and, therefore, that the presuppositions for data analysis are statistically violated. Further, this violation biases study results in such a way that measured stress levels are overestimated. A proposed alternative scale with different LTs shows nearly equidistant response categories. To solve the problem of equidistance, a fuzzy analysis of response data is presented and compared to conventional analyses.

# Going beyond the headlines: Narratives mitigate intergroup empathy bias

**Emile Bruneau**

Massachusetts Institute of Technology, Cambridge, Massachusetts, United States

**Mina Cikara**

Massachusetts Institute of Technology

**Rebecca Saxe**

Massachusetts Institute of Technology

**Abstract:** Three Afghani civilians were killed in a drone strike in Khandahar.

People increasingly get their news from online sources, making it easy to see the world through the prism of headlines, instead of the longer story. What are the consequences of reading just a single sentence encapsulation of world events? We tested the effects of reading headlines versus longer narratives, about events happening to in-group versus out-group members, for people assigned to arbitrary competitive groups (Eagles or Rattlers). In four studies, reading just headlines exacerbated intergroup differences in empathy: feeling more empathy for in-group members, and more counter-empathic emotions (e.g. Schadenfreude) for outgroup members. Headlines encourage attending to, and therefore remembering, what group a person is from. However, the intergroup empathy bias can be mitigated by providing a short narrative about each individual, which draws attention away from group membership and towards the individuals experience.

# Ordered Information and Word Learning: An Associative Learning Perspective

**Joseph Burling**

University of Houston

**Hanako Yoshida**

University of Houston

**Abstract:** A computational associative learning simulation is implemented to gauge the role of temporally ordered information in regards to establishing differently weighted representations. Simulation comparisons are made between two approaches. One approach simultaneously learns multiple sets of cues, which are trained to be associated with their respective outcomes. The other approach separates training into temporally distinct early and late phases. Qualitative differences in weighted representations are observed between the two types of training. Asymmetrical learning of features occurs in the simulation with temporally distinct learning instances, and not in the simultaneous learning model. Negative associations are learned for specific cues when competing information is introduced at a later time point. These findings provide discussion about the influence of order effects in terms of word acquisition by attending to relevant features over time, and in general, the role cue competition in relation to temporal learning during early development.

# The Hierarchical Structure of Word Senses

**Hee-Rahk Chae**

Hakkuk University of Foreign Studies

**Do-Il Hong**

Hakkuk University of Foreign Studies

**Abstract:** One of the most controversial issues in lexical semantics is the distinction between polysemy and indeterminacy/vagueness. We need to figure out whether a set of meanings are realizations of multiple senses of a word or manifestations of a single sense. There have been proposed many diagnostic tests for the distinction. Although they are useful to some degree, none of them are without problems. One of the reasons for these problems is that not all senses are equal on their statuses: there are not only full senses but also sub-senses. It seems to be impossible to set up a fixed set of all-purpose criteria for the distinction. For example, the level of sense discrimination for information retrieval would not have to be as deep as that for inference. In this study, we will focus on characterizing the hierarchical nature of (Korean) word senses, in due consideration of the conceptual units which are building blocks of senses.

# Word Segmentation Difficulty in Fourth Graders with Low Reading Achievement

**Sau-chin Chen**

Tzu Chi University

**Jenn-Yeu Chen**

National Cheng Kung University

**Abstract:** A series of studies have advertized the benefit of word segmentation in Chinese sentences comprehension for children with reading difficulty. This study attempts to identify the major cognitive factor contributing to this developmental difference among the children with the same age. A sentence reading with word judgment task was designed for a group of children with reading difficulty and a control group of children with normal reading capacity. In each trial of word judgment, a stimuli sentence could follow a word appearing in the critical region, a word appearing in the critical region but without meaning, a word appearing in the uncritical region, or a word disappearing in the sentence. For the words in the critical region, there is a ambiguous segmentation between them, and the children takes more cognitive effort to deny the word without meaning. The current results show the only difference between the two groups on the words without meaning. After excluded the factors such as intelligence and vocabulary, the inefficiency of attention would be the critical to reading difficulty. An improvement method based on a cognitive processing of Chinese sentence reading is suggested in this presentation.

# Is the Proximate Unit in Chinese Word Production Motivated by the Visual Prompt of the Task?

**Train-Min Chen**

National Cheng Kung University, Tainan, Taiwan, R.O.C.

**Jenn-Yeu Chen**

National Cheng Kung University, Tainan, Taiwan, R.O.C.

**Abstract:** Previous word production research employing the implicit priming paradigm has shown that speakers can benefit from the advanced knowledge of the initial word form of the word to be produced. In Dutch and English, a single onset segment is sufficient to produce the benefit, but a complete syllable is required in Mandarin Chinese. The absence of an onset effect in Mandarin Chinese might have to do with the orthographic characteristics of the prompts, which are syllable-based and could have motivated the production system to place more emphasis on the syllable than on the segment. The present study employed the same paradigm but with spoken prompts in addition. It turned out that there was a syllable effect but not a segment effect, irrespective of the modality of the prompts. The findings suggest that the proximate unit in Mandarin Chinese word production is an intrinsic effect, and not an accidental, task-dependent artifact.

# **The Impact of Contextual Cues on Infant Categorization**

**I-Chen Chen**

National Cheng Kung University

**Marin Huang**

National Cheng Kung University

**I-Wen Yu**

National Cheng Kung University

**Pei-Ling Wang**

Taipei Municipal University of Education

**Jon-Fan Hu**

National Cheng Kung University

**Abstract:** When Infants perceive and categorize objects in natural environment, they would also found the contextual cues useful. Therefore, how this factor influences infant categorization is an important issue that worth further studying. Experiment in the present study used eye-tracking technique to accurately capture 6-month-old infants eye movements in a categorization task, investigating the role the contextual cues would play for categorizing animals and vehicles. The familiarity-novelty preference paradigm was adopted to assess infants performance of categorization. It was found that infants looked more to the pictures of vehicles than animals in both congruent and incongruent conditions during the familiarization phase. The results showed that object-context relations play a specific role in infant categorization.

Keyword: infant categorization, contextual cues, eye-tracking

# Knowing where to look: Conceptual knowledge guides fixation in an object categorization task

Lang Chen

University of Wisconsin-Madison

Timothy Rogers

University of Wisconsin-Madison

**Abstract:** Increasing evidence suggests that humans are not passive perceivers of the world but actively seek out perceptual information. A pressing question for cognitive science concerns how conceptual representations influence this active perception. To address this question, we investigated fixation patterns during visual object classification while manipulating the level of specificity at which a given item was categorized. Twenty-nine undergraduates verified whether a picture matched a preceding verbal label while their eye-movements were monitored. When pictures (e.g., beaver) were classified at a specific level (BEAVER), participants showed significantly increased dwell time to distinctive features (tail) but decreased dwell time to common features (e.g., face) compared to classification of the same picture at a general level (e.g. ANIMAL) although participants attended to both distinctive and common features in both conditions. The results suggest that conceptual knowledge can substantially influence how viewers direct their gazes and consequently focus on the relevant perceptual information.

# Mindset interacts with subjective knowledge but not fluency when affecting preferential judgment

Rongjuan Chen

Stevens Institute of Technology, Hoboken, NJ, United States

Yasuaki Sakamoto

Stevens Institute of Technology, Hoboken, NJ, United States

**Abstract:** Fluency can influence various judgments. When processing fluent information, people think more intuitively than when processing disfluent information. Recent research showed that mindset (abstract vs. concrete) would moderate fluency effects on consumers preference. Other research suggested that subjective knowledge (e.g. estimated price) could influence product judgment. In this work, we manipulated mindset (abstract vs. concrete) and the fluency of an advertisement of chocolates (easy vs. hard), tested subjective knowledge of price (high vs. low), and examined the effects of these factors on preference, measured by how much they liked the chocolates (liking), how desirable the chocolates were (desirability), and how much they wanted to eat the chocolates (wanting). We found direct effects of fluency and price, but not mindset, on preference. However, mindset interacted with price to affect liking and wanting. We conclude by discussing why mindset interacts with subjective knowledge, but not fluency, when affecting preferential judgment.

# A Study of the Syntactic Category of Rhetorical Questions

Hongbo Chen

Liaoning University of Technology

**Abstract:** A review of the literature on the study of rhetorical questions (RQs) shows that most of the previous studies are aimed to describe the pragmatic function, while the cognitive factor has been considered by relatively few researchers. The major goal of this study is to discuss the syntactic category of RQs under the Prototype Theory of Categorization. The author first set up a theoretical frame for analyzing RQs, suggesting that all grammatical structures are prototypical categories, which fall into a category of syntax, a category of semantics and a category of pragmatics and a category of syntax is a category of different semantic meanings and pragmatic functions expressed by the same syntactic form. An analysis of RQs shows that RQs and genuine questions are in the same syntactic category QUESTION because they share syntactic similarities. Keywords: rhetorical questions; the Prototype Theory of Categorization; syntactic category of RQs

# Eye Movement Patterns Reveal How Oriental People Group Objects

**Fan-Ning Cheng**

National Cheng Kung University

**Yi-Rong Wu**

National Cheng Kung University

**Jo Pan**

National Cheng Kung University

**Gert Westermann**

University of Lancaster

**Hsueh-Chih Chen**

National Taiwan Normal University

**Jon-Fan Hu**

National Cheng Kung University

**Abstract:** Past literature pointed out that oriental people tend to consider thematic relationship more than taxonomic relationship (i.e. group banana & apple together more than banana & ape) compared to western people for thematic relationship. However, how oriental people judge the relationship between objects by grouping remains unclear. An eye tracker device was used to examine whether oriental people group objects thematically as the first step to investigate the issue. It was further assumed that people would tend to look longer on the image pairs which are found surprising and unexpected since they group those objects based on specific relationship from an opposite direction. Twenty-three oriental background subjects completed the experiment. The results showed that oriental background participants do view taxonomic pairs significantly longer than the thematic pairs in terms of total fixation duration and total fixation count by which the earlier hypothesis is supported.

Keywords: oriental, eye-tracker, taxonomic, thematic, categorization

# **Reading and Writing Performance in School-aged Children with Specific Language Impairment or/and with Developmental Coordination Disorder Identified at Preschool Age**

**Rong-Ju Cherng**

Department of Physical Therapy and Institute of Allied Health Sciences, National Cheng Kung University,  
Tainan, Taiwan

**Hsiang-Chun Cheng**

Department of Physical Therapy, HungKuang University, Taichung, Taiwan and Institute of Allied Health  
Sciences, National Cheng Kung University, Tainan, Taiwan

**Jenn-Yeu Chen**

Department of Psychology and Institute of Cognitive Science, National Cheng Kung University, Tainan,  
Taiwan

**Chia-Liang Tsai**

Institute of Physical Education, Health & Leisure Studies, National Cheng Kung University, Tainan, Taiwan

**Miau-Lin Shen**

Department of Early Childhood Education, Asia University, Taichung, Taiwan

**Abstract:** Ninety-seven children with a diagnosis of specific language impairment (SLI: 43) or developmental coordination disorder (DCD: 41), or both disorders (13) at preschool and 323 typically developing (TD) children were tested with the Chinese Reading Achievement Test (CRAT) and the Basic Reading and Writing Test Battery (BRWTB) to measure their reading and writing performance when they were 7-8 years of age. The results showed that children with SLI scored lower on CRAT and BRWTB than TD children. Children with DCD scored similarly to TD children on the two reading tests, but scored lower on the writing subtest of BRWTB. The incidence of dyslexia in children with SLI, children with DCD, children with both disorders and TD children is 48.6%, 14.3%, 50% and 12.9%, respectively. Early assessment of the language and motor development in children at preschool may help to predict their reading and writing performance at the early years of schooling.

# The development of numerical comparison in 2- to 4-year-old children

**Pierina Cheung**

University of Waterloo, Waterloo, Ontario, Canada

**Mathieu Le Corre**

University of Waterloo

**Abstract:** Infants deploy two cognitive systems that support numerical thinking: one for representing small sets of objects ( $<4$ ) in parallel, and another for representing large, approximate numerical magnitudes ( $>4$ ). Despite infants demonstrated numerical competence, preschoolers fail to show which of two sets contains more elements until they have acquired some number word meanings (e.g., Brannon & Van deWalle, 2001). However, previous studies mixed up small and large numbers. The current study asked whether preschoolers failure depended on the number of elements in sets. Two- to 4-year-olds were shown either small or large numbers of rectangles, and were asked to choose the set that had more. We analyzed childrens performance based on their number word knowledge. Results found that children were better at comparing small than large sets, and numeral acquisition facilitated numerical comparison. Implications for the role of the two cognitive systems and number word learning in numerical comparison were discussed.

# **The examination of physiological factor on two context effects in multi-attribute decision making**

**Itsuki Chiba**

Rikkyo university, Niiza, Saitama, Japan

**Takashi Tsuzuki**

Rikkyo university, Niiza, Saitama, Japan

**Masashi Soma**

Rikkyo university, Niiza, Saitama, Japan

**Abstract:** This experiment used the attraction effect and compromise effect to test the influence of ingestion of sugar on reliance on intuitive, heuristic-based decision making. And also for a search of these occurrence mechanisms, we measured the eye movement and negative emotion of the subjects. In the context-dependent effect, a difficult choice between two options is swayed by the presence of a third (normatively irrelevant) alternative. Previous works showed that the attraction effect increase and the compromise effect decrease when people have depleted their mental resources performing a previous self-control task. Moreover, it is thought that the attraction effect arise for the aversion from the negative emotion which feel when the trade-off has been perceived. We replicated these findings and analyzed the eye movement and the negative emotion to test the difference of two context-dependent effects.

# **A Classroom Study of Learning to Evaluate Scientific Evidence**

**Clark Chinn**

Rutgers University, New Brunswick, NJ, United States

**Abstract:** One of the goals of education is to promote growth in reasoning; a critical subgoal is to promote competence in critically evaluating the quality of evidence (e.g., evaluating comparisons, soundness of measures, etc.). In a classroom experiment with 4 science teachers, 14 science classes, and 225 seventh graders, two methods of promoting growth in the ability to evaluate evidence were contrasted over 10 lessons in which students evaluated evidence to solve scientific problems. Half of the classes engaged in active reasoningextensive group and class argumentation about evidence quality. The other half engaged in active reasoning plus expert modeling; these students engaged in the same argumentation but also listened to and discussed short conversational exchanges in which scientists discussed how they evaluated evidence quality. Students in the active reasoning plus modeling condition outperformed students in the active reasoning condition. Implications for the development of reasoning and for instruction are discussed.

# Impact of Modified Cognitive Behavior Therapy on Children with Autism Spectrum Disorders

**Suvarna Chinta**

International Institute of Information Technology -Hyderabad

**Bipin Indurkha**

International Institute of Information Technology-Hyderabad

**Abstract:** Autism Spectrum Disorder (ASD) is Neuro Developmental in origin with triad deficit (DSM-IV, APA, 1994), co-morbid behaviors. Modified Cognitive Behavior Therapy (MCBT) techniques Multimodal program, Exposure Response prevention, have been proven successful for people with ADHD and OCD respectively. The present study aims at finding the impact of these techniques in the treatment of co-morbid behaviors (attention deficit, obsessiveness, repetitive-stereotypical behavior) in ASD. Twelve children (Age: Mean=6.25, SD=2.22) diagnosed with ASD selected, Pre-test conducted to assess co-morbid behaviors with ADHD Scale, BASIC-MR Behavioral Scale, Vineland Social Maturity Scale and Attention span (calculated time spent on a particular task), found no difference. Planned intervention with MCBT for 6 participants (experimental group), the rest 6 participants (control group) underwent traditional occupational, speech therapy. Total intervention is for a period of 16 weeks (45 minutes per day). End of 16th week post-test assessed a significant improvement in behaviors. Concludes effectiveness of MCBT ( $p < 0.001$ ).

# Can Articulating Aloud Offset Effects of Listening to L1 in a Foreign Accent?

**Kit Cho**

The University at Albany, SUNY

**Laurie Beth Feldman**

The University at Albany, SUNY & Haskins Labs

**Abstract:** The production effect refers to the finding that words that are read aloud are more distinctive and memorable relative to words that are read silently. The present study explored the production effect using auditory stimuli, spoken in two different accents. American participants repeated a word or listened passively to words spoken in either their native accent (English) or a foreign accent (Chinese). In both recall and recognition, memory was better for words that were read aloud rather than listened to, thereby extending the production effect from the visual to the auditory domain. However, the benefit to recognition associated with repeating a word, rather than listening to it, was greater in a native accent.

Evidently, the gestures of articulating a word aloud benefit memory but its impact is attenuated by phonetic mismatch between what participants hear and what they produce.

# Blending Narrative Spaces of the Flashback Scenes in the Joint Security Area

**Hye Rhang Cho**

Sogang University

**Seung Suk Nam**

Sogang University

**Sook Whan Cho**

Sogang University

**Abstract:** The film, Joint Security Area (2000), centers on a cross-border shooting incident in the flashpoint of North-South tensions. As Major Sophie Jang's investigation develops, she uncovers evidence suggesting that neither account from North and South is correct. With the use of extended flashbacks, the truth about the incident, as well as the unlikely connection between the North-South Korean soldiers, discloses. This paper is intended to propose a model of narrative blending associated with the mapping between the investigators and the suspects spaces in terms of intentionality and analogy (Fauconnier and Turner, 2002). It will be seen that the contradicting accounts of the soldiers are associated with their intentions, involving memory and fear, this input spaces of soldiers interacting with another input space of Jang. As the relations of analogy and intentionality are exhibited in the input spaces and compressed, the friendship between the soldiers reveals in the blended space.

# Blending Narrative Spaces of the Reenactment Scenes in the Thin Blue Line

**Sook Whan Cho**

Sogang University

**Seung Suk Nam**

Sogang University

**Hye Rhang Cho**

Sogang University

**Abstract:** In *The Thin Blue Line*, the story of a man (Randall Adams) convicted and sentenced to die for a murder that he did not commit, Morris (1988) presents a series of interviews demonstrating the investigations, creating reenactment scenes of the shooting built from the testimony and recollections of the detectives, suspects (David Harris), and witnesses involved in the murder. This paper is intended to propose a model of narrative blending associated with the mapping between the investigator and the suspect spaces in terms of intentionality (Fauconnier and Turner, 2002). It will be seen that Harris's failure to tell the truth explicitly is associated with his intentions and mental attitudes involving desire and fear; this input space of Harris's deceiving intention interacting with another input space depicting his criminal record and violent traits. As his intention is revealed in these space interactions, Harris is found guilty in the blended space.

# **Ten-month-old Infants Prefer Comforters, not Helpers**

**Hiu-Mei Chow**

Department of Psychology, The University of Hong Kong

**Stephanie Jui-chi Chen**

Department of Psychology, McGill University

**Geroldene Tsui**

Department of Psychology, The University of Hong Kong

**Ping-Hui Chiu**

Department of Psychology, The University of Hong Kong

**Chia-huei Tseng**

Department of Psychology, The University of Hong Kong

**Abstract:** Preverbal infants prefer characters that help others in achieving a goal (e.g. climbing up a hill), but how this preference is established remains unknown. In current study, we examined physical and emotional outcome hypotheses by presenting 6- and 10-month-old infants a social interaction similar to what was used in Hamlin et al. (2007). During the learning habituation stage, an agent emotionally comforted or upset a climber by pushing it up (helped) or down (hindered) the hill (physical outcome). On a new platform, we found that 10-month-old infants looked significantly longer when the climber approached the comforter who previously made the climber laugh regardless of what physical outcome was. This indicates infants prioritization of emotional over physical outcome and their consideration of a third partys internal state in forming a social preference, which was absent at 6-month-olds. This leads to the conclusion that this prioritization is unlikely to be innate.

# Comprehension of Representational Gestures

Kawai Chui

National Chengchi University

**Abstract:** In daily communication, the spontaneous use of hands and arms along with speech is pervasive and indispensable. The present study used real face-to-face communication materials as stimuli to investigate the comprehension of representational gestures when speech is not available. Twenty-two adults watched short, soundless video clips extracted from recordings of daily conversations, each including a spontaneous representational gesture. Participants were requested to judge whether and in what way the gestures made sense. Their responses showed that in the absence of speech, the idiosyncratic hand configurations were not incomprehensible, suggesting that speech-gesture integration is not entirely obligatory. The way representational gestures were understood in this study reveals the activated content of the gestural-action representations which consists of conceptual knowledge associated with a situation of use.

# Task-specific conflict monitoring and cognitive control in the prefrontal cortex

**Chongwook Chung**

KAIST, Daejeon, KOREA

**Chobok Kim**

Kyungpook National University, Daegu, KOREA

**Jeounghoon Kim**

KAIST, Daejeon, KOREA

**Abstract:** According to the conflict monitoring theory, the dorsal anterior cingulate cortex (dACC) and the dorsolateral prefrontal cortex (DLPFC) are involved in detecting (i.e., monitor) and regulating (i.e., controller) the conflict, respectively. However, it has been unknown whether different types of response conflicts recruit the same monitor-controller loop. To address this issue, we developed a double-response-conflict task using color-based and location-based conflict stimuli. This task evoked two types of conflict at the response level either simultaneously or separately, and we tested neural activities in dACC and DLPFC employing the conflict adaptation paradigm. Along with behavioral task-specific conflict adaptation effects, imaging results showed task-specific conflict adaptation in dACC and DLPFC. The results also demonstrated that double-conflict processing appears to be qualitatively different from single-conflicts despite the fact that the sources of double-conflict were overlapped with two single-conflict conditions. These suggest that response conflicts from two different sources are independently processed.

# **The Development of Orthographic Awareness for Radical Properties of Chinese Characters in Young Children**

**Yi-Ling Chung**

National Cheng Kung University

**Pei-Yu Luo**

National Cheng Kung University

**Hsueh-Chih Chen**

National Taiwan Normal University

**Li-Yun Chang**

University of Pittsburgh

**Jon-Fan Hu**

National Cheng Kung University

**Abstract:** Radical properties are thought as important roles in Chinese character perception. Understanding radical knowledge is useful for learning Chinese vocabulary. However, the previous results investigating radical frequency or radical position showed inconsistent conclusions. Therefore, the present study focuses on manipulating radical position-based frequency and character-like degrees to examine the effects of the regularity of the two properties on Chinese character recognition. 210 Chinese-speaking elementary students were asked to judge if one of the two words are more likely to be legal word from 123 paired Chinese pseudo-words. The results indicates that: (a) there is a radical position regularity effect on orthographic awareness, which means the accuracy of high frequency radical is better than low frequency; (b) children can identify radical position regularity; (c) the ability of radical position awareness turns into stable through the experience of character recognition growing.

Keywords: orthographic awareness, radical, position/frequency regularity, Chinese learning

# The Dynamics of Sentence (In)comprehension

**Gregory Cox**

Indiana University

**Melody Dye**

Indiana University

**Seth Frey**

Indiana University

**Abstract:** Comprehension of text develops over time, such that a single word may lead to the activation of different concepts and thus different expectations at different times after it is encountered. Since the pioneering work of Neely (1977), much evidence has been found that multiple senses of a word are activated shortly after it is encountered, but that senses that are contextually irrelevant are later inhibited. This has implications for the processing of anomalies in sentences, including malapropisms like switching antidote for anecdote: if the anomaly is primed by the semantic context (e.g., it is preceded by the word doctor) shortly before it is encountered, it should be less likely to be noticed by the reader and is less likely to impede reading (and comprehension) of the sentence. We present results from a reading-time study using sentences in which malapropisms are presented in either neutral or semantically congruent contexts, with the semantic prime at varying distances from the anomaly (e.g., doctor, above). These results are interpreted within a dynamic sentence comprehension model based on the attractor model of Tabor, Juliano, & Tanenhaus (1997).

# **Aquisition of multipliers: learning a new class of number**

**Meghan Dale**

University of Waterloo

**Mathieu Le Corre**

University of Waterloo

**Abstract:** Acquisition of number words has been examined in great detail for the count list of one through nine, but rarely do multi-digit numbers receive any study (Carey, 2009; Fuson et al., 2007). In English, once we pass into triple digits, we encounter a new class of number: multipliers. Multipliers are characterized by the unique syntactic structure of number + multiplier + noun(pl). 27 children aged 4 to 6 years old were taught a novel word (gobi) using the multiplier structure. After being trained to identify one gobi objects, children were tested on their ability to generalize gobi in four additional contexts. Participants fell into one of two distinct groups that either consistently passed or failed all tasks ( $t(25) = 13.406$ ,  $p < 0.001$ ). We conclude that prior to formal education children are able to identify the multiplier structure with minimal exposure and discuss implications for childrens acquisition of multi-digit numbers.

# Describing faces: conventionalizing ontologies through dialogic interaction

**Nicolas Davidenko**

Stanford University

**Gregory Mills**

University of Edinburgh

**Abstract:** Although we are highly efficient at remembering and recognizing faces, we find it remarkably difficult to describe faces to others. This stems in part from the holistic nature of face representation and the difficulty of expressing configural information in words. However, research on dialogic interaction has shown that when interlocutors encounter a domain for which they possess only vague descriptions, they rapidly conventionalize ad-hoc ontologies that enable efficient and systematic communication. To test the hypothesis that interlocutors will conventionalize ad-hoc ontologies for describing faces, we present data from a collaborative, computer-based task which is played by pairs of participants. Successful completion of the task requires participants to interactively describe and identify target faces from a set of distractors. The data provide evidence of dyads conventionalizing ontologies for referring to faces. Drawing on the observed interactions, we demonstrate how these conventions emerge as a consequence of participants resolving instances of miscommunication.

# **The effect of speakers identity on syntactic processing: Evidence from verb-gender agreement in Slovak**

**Doug J. Davidson**

Basque Center on Cognition, Brain and Language

**Adriana Hanulikova**

Basque Center on Cognition, Brain and Language

**Manuel Carreiras**

Basque Center on Cognition, Brain and Language

**Abstract:** An important property of speech is that it explicitly conveys speakers identity. Although previous studies have shown that speakers identity affects semantic processing, the influence of speakers identity on grammatical processing is less clear. Here we investigate subject-verb agreement in Slovak, when the agreement depends on the speakers gender (as cued by his/her voice) compared to when it depends on the formal grammatical gender of the subject.

We compared ERP responses to Slovak verbs disagreeing with the formally-marked subjects gender (e.g., (the) mother-in-lawFEM \*stoleMASC plums), and to verbs disagreeing with subjects gender as conveyed by the speakers voice (e.g., IFEM \*stoleMASC plums).

The formally-marked subject and verb disagreement resulted in a P600 preceded by an anterior negativity. However, disagreement based on the speakers voice elicited a posterior negativity but no P600. We will discuss differences in checking or repair mechanisms of these two agreement types.

# Joint Evaluation and Trend Information Mitigates the Disposition Effect

**Kyung Soo Do**

Sungkyunkwan University

**Hee-Yeon Kim**

Sungkyunkwan University

**Rae-yeop Park**

Sungkyunkwan University

**Abstract:** Disposition effect refers to the phenomena where investors hold loser stocks and sell winner stocks. Effects of information about the trend on the disposition effect were tested in two experiments, where participants decided whether they sell or not, given information about the performances of one (separate evaluation, SE) or two stocks (joint evaluation, JE). When only the prices of the previous month and the current month were given in Experiment 1, the percentage of selling the losing stock in JE was twice larger than that in SE. The differences in selling the losing stock between SE and JE disappeared when the monthly prices of previous six months were given in Experiment 2. Results of the two experiments showed that the disposition effect got weaker when the trend of loss was apparent either by knowing the losing performance over many stocks or over many months.

# Effects of Scaffolded Feedback and Confidence of Incorrect Answers on Retention

**Kyung Soo Do**

Sungkyunkwan University

**Hanna Kim**

Sungkyunkwan University

**Abstract:** The effects of scaffolded feedback and confidence of incorrect answers were tested in two experiments. As feedback imposes cognitive load, an effective feedback should help reducing the cognitive load. One possible way of reducing the load is using scaffolded feedback, in which hints are incrementally provided until participants generate the correct answer. Scaffolded feedback promoted learning and reduced the cognitive load more than the corrective feedback in Experiment 1, in which knowledge of Korean history was tested. The advantage of the scaffolded feedback disappeared when text comprehension was tested in Experiment 2. However, errors with high confidence are corrected more than errors with low confidence in both experiments. The results of the two experiments show that the scaffolded feedback promotes learning only when the cognitive load of the target task is not large.

# Computing Humorous Metaphors

**Pawel Dybala**

JSPS Research Fellow / Otaru University of Commerce

**Kohichi Sayama**

Otaru University of Commerce

**Abstract:** It was experimentally showed that humorous texts can be explained using approaches applied to metaphors, such as the salience-imbalance or the domain-interaction approach. It was also demonstrated that humorous metaphors often include a switch between positive and negative emotions.

We propose to construct a computer system able to understand and generate such metaphors. Currently we are constructing a metaphor conceptual network, in which links between concepts are calculated accordingly to their roles in metaphor understanding. This will allow the computer to process metaphors. Next, we will adjust the links distance calculation to match the humorous metaphors (to increase the salience-imbalance, as demonstrated in existing research). We will also use an emotiveness-recognition-system to detect emotive associations towards particular phrases, in order to choose pairs with the emotional switch.

The system will be evaluated in user-oriented experiments.

# Expanding the Transformation Paths in a Mutual Transformation Mechanism of Music and Narrative

**Jun Endo**

Iwate Prefectural University, Iwate, Japan

**Taisuke Akimoto**

Iwate Prefectural University, Iwate, Japan

**Takashi Ogata**

Iwate Prefectural University, Iwate, Japan

**Abstract:** Music is an important part in the narrative generation system we have been studying, but is not merely the accompaniment of narrative. For the integration of the knowledge and techniques of narrative and music, we developed some versions of the automatic mechanisms which mutually and cyclically transform narrative structures and musical structures using narratological and musical methods. A previous prototyping system consists of various transformation modules: a music composition mechanism from a narrative or a story, a music variation mechanism from an original music, a transformation mechanism from variation music to the narrative discourse, etc. This paper's goal is to add other possible circulation paths to expand the system framework. Specifically, we implement a new original music generation mechanism by the re-formation of the original music anew and add a transformation mechanism from variation music to the new original music. Moreover, we are evaluating the corresponding relationship between narrative and music, and the quality of generated music.

# Eye tracking differences in respondent behaviour across multiple survey modes

**Tom Foulsham**

University of Essex

**Olena Kaminska**

University of Essex

**Abstract:** Research into survey methodology has revealed that respondents answer differently depending on the way in which questions are presented. To date there have been few empirical attempts to relate these differences to respondents cognition. To investigate this, we used eye tracking in three different survey modes: a computer-based mode, a pen-and-paper questionnaire and a face-to-face interview with show-cards. This novel method of obtaining cognitive measures across modes means that we are able to investigate attention and cognitive processing by coding which questions and answers are looked at the most in the different settings. The results confirm the attentional biases linked to some responses, such as a bias to the first and last response options in a list, as well as revealing differences in how response options were inspected across modes. These results are discussed and it is proposed that cognitive science can play a significant role in survey methodology.

# **Automatic facilitation of social behavior by implicit inferring of social intention**

**Haruaki Fukuda**

Aoyama Gakuin University

**Hiroaki Suzuki**

Aoyama Gakuin University

**Ayumi Yamada**

Aoyama Gakuin University

**Abstract:** It is known that we can infer others intentions and goals automatically. On the other hand, recent researches have demonstrated that people spontaneously adopt and pursue the goals perceived in others behavior. This phenomenon is called goal contagion and goal contagion can occur even when the goal is not consciously understood. In this study, we examined whether mere exposure to animated agents intentions could influence our social behavior. Participants performed social game while the short animation depicting social intention in the peripheral monitor that participants did not attend to. We found that participants exposed to an animation that implied helping behavior was more cooperative than participants exposed to an animation that implied hindering behavior. In addition, participants could not answer what was displayed in the peripheral monitor in which the animation was displayed. These results suggest that others intentions can influence our social behavior without consciousness.

# Quantifying linguistic coordination

**Riccardo Fusaroli**

Aarhus University

**Kristian Tyn**

Aarhus University

**Abstract:** Language has been defined as a social coordination device (Clark 1996) enabling innovative modalities of joint action. However, the exact coordinative dynamics over time and their effects are still insufficiently investigated and quantified. Relying on the data produced in a collective decision task (Bahrami et al 2010, Fusaroli et al. 2012) we extend to linguistic coordination dynamical measures of recurrence employed in the analysis of sensorimotor coordination (such as heart-rate (Konvalinka et al 2011), postural sway (Shockley 2005) and eye-movements (Dale, Richardson and Kirkham 2012). We employ nominal recurrence analysis (Orsucci et al 2005, Dale et al 2011) on the decision-making conversations between the participants. We report strong correlations between various indexes of recurrence and collective performance. We argue this method allows us to quantify the qualities of linguistic coordination and their effects at a fine-degree.

# How a Quantum Approach to Memory Incorporates Contextuality and Potentiality

**Liane Gabora**

University of British Columbia

**Kirsty Kitto**

Queensland University of Technology

**Abstract:** Existing models of memory incorporate context in only a limited sense, and they fail to accommodate the complementary notion of potentiality. Humans use context in a multitude of ways: (1) to resolve ambiguity between alternative pre-existing meanings, (2) to emphasize particular aspects of something, (3) to identify new and potentially meaningful relationships, and (4) to clarify an idea such that ones understanding of it goes from ill-defined to well-defined. A powerful model of memory must capture all four. Drawing on elements of vector based information retrieval models, Grdenfors geometric model of conceptual space, and matrix model of memory, we present a quantum approach to memory, and show how it can capture these four senses of contextuality. Though in its infancy, the quantum approach can provide not just exceptionally high-density memory storage but creative capacities as well.

# The Naturalization of Concepts between Computational Intractability and Cognitive Theories

Francesco Gagliardi

University of Rome "La Sapienza"

**Abstract:** In this work we present some computational considerations about the nature of concepts. After a first distinction between "per se" concepts and the epistemic or psychological aspects of concepts we focus our attention on this latter by linking their understanding to the formalization of automatic classification problems as developed in machine learning field.

We show how the problem of categorization and of formation of concepts representing categories, has to be considered a computationally intractable problem that hence can be faced only with heuristic strategies. In this perspective the different cognitive theories proposed in cognitive science to explain categorization processes (e.g. the prototype-theory by E. Rosch), can be considered as different heuristic strategies (computationally tractable solutions) to face the categorization problems and that the human mind uses in order to prevent an unsustainable cognitive-computational load.

Finally, we frame these ideas in the cognitive naturalism and in the current viewpoint that considers the most of the human reasoning as heuristic solutions to intractable problems. Our thesis is that concepts can be considered as heuristic and perspective solutions that any intelligent system, such as human mind, finds in order to represent categories using limited resources and capacities by which it organizes and gives a sense to the large variety of reality that surrounds it.

# Selection of decision rules in dynamic decision making

**Jean-Francois Gagnon**

Universit Laval

**Marie-ve St-Louis**

Universit Laval

**Sebastien Tremblay**

Universit Laval

**Abstract:** This study investigates how dynamic complexity influences the use of heuristics in a dynamic decision making task. 24 subjects performed a computerized task that required them to predict the dynamic change ( $t+1$ ) of discrete interrelated variables (range 0-20). There were four experimental sessions that involved the co-evolution of eight variables over 40 time periods. The level of complexity of the dynamic change of each variable was determined by its distance to linearity. Five heuristics, characterized by different methods of effort-reduction (Shah & Oppenheimer, 2008), were formalized. Forecasting performance of participants was compared against each heuristic. The results revealed that subjects adapt their heuristics to the level of dynamic complexity. Our findings are discussed in relation to the conditions under which individuals adapt decision rules in complex dynamic tasks and on the consequences of such heuristic changes (Hogarth & Karelaia, 2007).

# Annual Cognitive Modeling Competition

**Kevin Gluck**

Air Force Research Laboratory

**Abstract:** Although the cognitive and behavioral modeling communities now have a rather lengthy history and there is ongoing research and development in these areas across dozens of academic, industrial, and government research laboratories, very little of the work has been explicitly competitive. That said, there are precedents for modeling competitions in this area. Two examples include the PokerBot Competition and the Dynamic Stocks and Flows Model Comparison Challenge. Both of these were successful and interesting events. They were also both single shot modeling competitions that did not evolve into annual events in the spirit of something like Robocup or the NIST-sponsored automated speech recognition competitions. It is time to consider a recurring annual cognitive modeling competition. This poster is an opportunity for community discussion of the pros, cons, infrastructure requirements, and design parameters that should be considered in developing such an event within cognitive science.

# Do Young Children Habituate to their Classroom Environment?

**Karrie Godwin**

Carnegie Mellon University

**Anna Fisher**

Carnegie Mellon University

**Abstract:** Prior research has shown that visual features of the classroom environment (e.g., charts, posters) can be potential sources of distraction hindering children's ability to attend to the content of a lesson. However, it is possible that over time children may habituate to their classroom environment. To address this possibility we investigated whether more prolonged exposure in a high visual distraction learning environment would result in habituation. We presented 23 kindergartners with 10 science lessons over 2-weeks. A habituation effect was observed as evidenced by a significant decrease in the proportion of time children attended to the environment between week 1 and week 2 ( $p=0.001$ ). However, the proportion of time children attended to the environment at week 2 remained significantly above baseline levels ( $p<0.0001$ ). Thus over time children began to habituate to the classroom environment; however, the environment remained a significant source of distraction for young children.

# Phonological neighbourhood clustering effects on verbal short-term memory

Winston Goh

National University of Singapore

**Abstract:** Phonological similarity between words as measured by neighbourhood density counts the number of words differing from the target word by a single phoneme. The word cat has a denser neighbourhood (e.g. hat, cut, at, scat) than the word wag (e.g. bag, wan). However, density does not capture between-neighbour relationships (hat and at are also neighbours of each other, but bag and wan are not). A recent index called the clustering coefficient measures the proportion of neighbours of a word that are also neighbours of each other. In an immediate serial recall task of 6-word lists using non-repeated sampling, lists of words with high clustering coefficients (i.e. many neighbours were neighbours of each other) were better remembered than those with low clustering coefficients (i.e. few neighbours were neighbours of each other). The findings suggest that a network of overlapping similarities among a to-be-remembered words phonological neighbourhood enhances recall in short-term memory.

# Children's sensitivity to informant's inductive efficiency and learner's epistemic states in pedagogical contexts

**Hyowon Gweon**  
MIT

**Patrick Shafto**  
University of Louisville

**Josh Tenenbaum**  
MIT

**Laura Schulz**  
MIT

**Abstract:** Children use properties of information and epistemic states of others to socially evaluate informants in pedagogical contexts. Recent studies have shown that in pedagogical contexts, children expect teachers to provide information to support accurate inference. Do children simply prefer teachers who provide more information, or do they rationally expect teachers to provide the right amount of information? Here we present a computational model of social learning that incorporates the cost of acquiring information and a series of experiments with children (5- and 6-year-olds) to test its predictions. Children observed two teachers who either provided a minimal amount of information or exhaustive information about a multi-function toy to a nave learner. Consistent with the predictions of the model, childrens preferences rationally reflected the informativeness of the teachers demonstrations, the cost of observing the demonstrations, and even the learners epistemic state. Taken together, the results suggest that learners can use information provided by others to not only learn about the target object but also to rationally evaluate others in order to guide their future choices of informants.

# The End is Near: Anticipating the end of a sentence

Lance Hahn

Western Kentucky University

**Abstract:** Hahn (2011) demonstrated that anticipating a final word from local context benefitted from the knowledge that the sentence was ending. In this work, I hypothesized that statistical regularities of text usage would show a building anticipation of the sentences end as the ending word sequence is acquired. A text corpus analysis was conducted focusing on 570 common and 570 uncommon sentence endings. A single word ( $w_1$ ) followed by three unspecified intervening words generated a weak average anticipation ( $p(w_5 = \cdot \mid w_1 \text{ ? ? ?}) = 0.1$ ) that steadily increased with the accumulation of subsequent words in the ending sequence. The complete four-word context generated a strong average anticipation ( $p(w_5 = \cdot \mid w_1 w_2 w_3 w_4) = 0.8$ ) of the subsequent period that renders the period fairly redundant.

# **Individual differences and phonetic aptitude in the earliest stages of L2 acquisition**

**Adriana Hanulikova**

Basque Center on Cognition, Brain and Language

**Dan Dediu**

Max Planck Institute for Psycholinguistics

**Zhou Fang**

Donders Institute for Brain, Cognition and Behaviour

**Jana Basnakova**

Slovak Academy of Sciences

**Falk Huettig**

Max Planck Institute for Psycholinguistics

**Abstract:** Most learners of a foreign language (L2) struggle to acquire a native-like accent. We explored how a training study of learning consonant clusters at the very onset of the L2 acquisition can inform us about L2 learning in general and individual differences in particular. Dutch native (L1) speakers were trained on Slovak words with consonant clusters. In the session following training, participants were tested on a battery of L2 perception and production tasks. The battery of tests was repeated twice more with one week between each session. An additional battery of control tests was used to test participants L1 skills. Participants showed considerable individual differences across all L2 tasks, stable across sessions. Two participants showed L2 production performance that fell within 2 standard deviations of the mean ratings obtained for an L1 speaker. The mispronunciation detection task was the only perception task, which significantly predicted production performance in the final session.

# What do numbers tell you? The effects of data-presentation design on the prolonged use of health-related life-log tools

**Etsuko T. Harada**

University of Tsukuba

**Satomi Yoshiyama**

Hosei University

**Abstract:** Although a number of life-log tools for health care have been proposed, they share a common problem; the drop-out problem of achieving long-term continuous usage in users. Providing numerical data is believed to be useful in tackling the problem, but, that can also have adverse effects if people overly react or misinterpret the meaning of the data. To investigate how people react to numerical data, we asked 817 undergraduate students to evaluate some fictitious tools for four domains (e.g., blood pressure) with one of five different designs; with standard or precise figures (with two additional digits), combined with/without interpretive messages for the data (e.g. good condition), or no numerical data (message only). The results indicate that involvement in health-care activities is independent of tool evaluation, such that only tool evaluations were strongly influenced by the existence of numerical data. The merits and demerits of numerical presentation are discussed.

# Japanese script types in written names create the images of their referents

**Aya Hatano**

Nagoya University

**Masahiro Amagase**

Nara Women's University

**Jun Kawaguchi**

Nagoya University

**Abstract:** This study investigated how the unknown objects names written in different Japanese script types (Hiragana, Katakana, and Kanji) would create the images of their referents. Previous studies suggested that writers would creatively use the script types for communicating emotional semantic information to readers. Although there are various factors affecting images of referents, how the factors have effects on them has not been investigated sufficiently. We presented Japanese undergraduates with 10 names of ethnic foods unknown to them. The participants read each name written in one of three script types and described the images of its referent. Their descriptions were analyzed by KH Coder (a freeware for text mining). The result shows the images of referents are influenced by the Japanese writing system, general visual features of each script type, and phonological features of words.

# **Is past information useful for evaluating present covariation information? : Effect of irrelevant information on causal judgment**

**Ikuko Hattori**  
Ritsumeikan University

**Masaki Hattori**  
Ritsumeikan University

**Abstract:** This study examined how information about the past affects the estimation of present covariation in causal judgment. For example, although lottery stands advertise that they sold the tickets of a big win last year, and buyers tend to buy tickets there, winning the prize this year has no actual connection with past win. However, information about the past has a psychological influence on people in causal judgment. In this experiment, participants observed this year's records of fictitious baseball players and estimated their contract money for the next season. Participants were assigned to either powerful-team or weak-team condition, and were told that their team had finished among the best three or the worst three for ten years. Weak-team group tended to significantly discount the contribution by the player concerned. The result implies that past information should be concerned with dealing the non-cause cases in which the target cause does not occur.

# Visual cognition of "speed lines" in comics: Experimental study on speed perception

**Hiromasa Hayashi**

University of Tokyo, Meguro-ku, Tokyo, Japan

**Goh Matsuda**

University of Tokyo, Meguro-ku, Tokyo, Japan

**Yoshiyuki Tamamiya**

University of Tokyo, Meguro-ku, Tokyo, Japan

**Kazuo Hiraki**

University of Tokyo, Meguro-ku, Tokyo, Japan

**Abstract:** "Speed lines" is the abstract lines used in comic to make objects look like they're moving. The number and the length of speed lines are manipulated by comic artists to match the speed they want to express, but few studies have tested their effect on perception of motion of the viewer. To investigate the matter, we conducted an experiment employing prediction-motion task. 19 participants were shown an apparent motion of a ball moving in uniform linear motion, and were told to estimate the speed of the ball. Each ball was presented with one of six patterns of speed lines, 3(number) x 2(length). As result, we found that both the number and the length of speed lines have significant effect on subjective speed of the ball. This indicates that the number and the length of speed lines indeed affects viewer's perception of motion, thus plays significant role in comics.

# Ontology Architecture of a Neuro-psychoanalytical, Computational Model

Isabella Hinterleitner

ICT

**Abstract:** The paper introduces the ontological knowledge architecture of the psychoanalytical, hierarchical and computational model ARS (Artificial Recognition System). The ontology architecture of the model is represented by a knowledge base. Semantic and individual memories are realized by means of an ontological architecture. These memories are modeled in a triple notation by the knowledge representation languages Resource Description Framework (RDF) and Resource Description Framework Schema (RDFS). Additionally, rules are employed for reasoning in the semantic knowledge base (manipulation rules) and individual knowledge base (action rules). The approach uses RDF and RDFS for the representation of metadata describing the semantic and individual memories. The simulation shows that general concepts are needed to form semantic memory as such. In addition, individual instanced memory is needed for forming individual memory. In conclusion, the ontological approach can be further transferred to the field of building automation by representing domain-specific ontologies (individual) and upper ontologies (semantic).

# **The absence of phonetic symbolism to the novel speech sound -comparison of cross-modal correspondence between Chinese and Japanese speakers using Chinese speech sound-**

**Sachiko Hirata**

The University of Tokyo

**Shinichi Kita**

Kobe University

**Abstract:** Phonetic symbolism is a phenomenon that speech sound evokes images based on sensory experiences and thus often discussed with the similarity for cross-modal correspondence. Hirata and Kita (2012) showed cross-modal congruence between brightness/darkness and Chinese speech sound with and without aspiration in Chinese speakers by using Garner's task. In the present study, we examined whether Japanese speakers, which do not have any Chinese knowledge, show cross-modal correspondence to the Chinese speech sound or not. We conducted the same experiment as previous research to Japanese speakers with no Chinese experience. As a result, Chinese speech sounds with aspiration, which resemble voiceless consonants, were not matched with brightness, whereas those without aspiration, which resemble voiced consonants, were not matched with darkness. This result is different to its pattern in Chinese speaker and consequently suggests that phonetic symbolism is affected by the knowledge of the phonemes of its language.

# Longitudinal observation of action slips: A case study of a young child

Naoya Hirose

Kyoto Notre Dame University

**Abstract:** The purpose of this study was to investigate action slips during acquisition of a new skill. Whereas most studies on slips have collected action errors of adults using the diary method, we observed a young child's daily performance using video recordings. One child's mouse rinsing activities after toothbrushing were recorded for one year from age four to five, and analyzed in terms of action slips as well as microslips—miniature versions of slips. Slips were repeatedly observed when a child took a cup and filled it with water. Quarterly analysis reveals that the total number of slips did not decrease monotonously: whereas two types of slips, commissions and adjustments, decreased over one year, other types increased from Q1 to Q3, then decreased in Q4. This suggests that in the process of the skill acquisition some types of slip may fade out, but others may rise or last out.

# **The role of social contexts in adults' word learning**

**Masako Hirotani**

Carleton University

**Koji Shimada**

National Institute for Physiological Sciences

**Shuntaro Okazaki**

National Institute for Physiological Sciences

**Hiroki C. Tanabe**

National Institute for Physiological Sciences

**Norihiro Sadato**

National Institute for Physiological Sciences

**Abstract:** While numerous studies report the significance of social contexts in infants word learning, data concerning adults are scarce. This study aims to fill this gap. Specifically, it investigated the extent to which a number of the parameters associated with joint attention (e.g., direction and timing of eye-gaze between learners and target objects) help adults learn new words (i.e., map new objects with new labels). The study adopted a novel experimental paradigm where live interactions between two learners took place in four different learning contexts. An eye-tracker recorded learners eye-gaze during the experiment. Adult learners learned new words most successfully when they shared both the direction and timing of their eye-gaze towards the target objects. In addition, word learning initiated by a learner alone, without sharing eye-gaze with another, failed to match these results. Overall, this study supports the view that joint attention maximizes adults learning of new words.

# **A Cognitive-Educational Approach to the Verb mek-ta in Korean**

**Do-Il Hong**

Hankuk University of Foreign Studies

**Hee-Rahk Chae**

Hankuk University of Foreign Studies

**Abstract:** This study tries to analyze the basic and extended meanings of the Korean verb mek-ta 'to eat' from a cognitive point of view. The most basic meaning of the verb is 'to pass food and others through the mouth into the stomach'. This meaning has been extended to other intransitive and transitive verb meanings and auxiliary verb meanings. When presenting the verb to learners of Korean as a Foreign Language (KFL), it should be presented so that learners themselves can infer the extended meanings using a semantic network. To this end, uses of those words meaning 'to eat' in the native languages of KFL learners should be investigated, and common meanings with the Korean verb should be identified. Then, we can create a semantic network of the senses of 'to eat', a network of the basic meanings and extended meanings of mek-ta in Korean and corresponding verbs in other languages.

# Connectionist Modeling of Frequency and Regularity in Mandarin Relative Clause Processing

**Yaling Hsiao**

University of Wisconsin-Madison, Madison, Wisconsin, United States

**Maryellen MacDonald**

University of Wisconsin-Madison

**Abstract:** Studies of Mandarin relative clause processing have yielded mixed results. Subject relatives (SRCs) are found more frequent than object relatives (ORCs) in corpora; however, the word order of ORCs resembles canonical SVO simple sentences. The present study examined the experienced-based effect of structural frequency and regularity by conducting a simulation in a simple recurrent network, trained on 10000 simple and RC sentences, in the proportions found in Chinese Treebank 7.0. The model contained 18 input and output units and 36 hidden and context units. Network performance was assessed on the level of grammatical prediction error of the next word. Following 10000 training epochs, ORCs performance showed garden-pathing upon encountering disambiguating relativizer due to resemblance to the SVO order in the beginning. For SRCs, which have an irregular verb-first structure, error was high but dropped later at the relativizer, showing sensitivity to language statistics. Results reflect both frequency and regularity effects.

# A Corpus Survey of Chinese Individual Classifiers

**Shuping Huang**

National Sun Yat-sen University, Kaohsiung, Taiwan

**Jenn-Yeu Chen**

National Cheng Kung University

**Abstract:** As of today, there are scarce studies that show us how classifiers are used in real life. While information technology progresses, today's researchers are privileged to use large-size databases to explore the real usage of classifiers. We selected 386 concrete nouns in Chinese, and looked them up in Chinese GigaWord for their collocating classifiers. Seventy individual classifiers were found to pair up with these 386 nouns. The following questions are of our particular interest: (1) What are the most frequent classifiers in Chinese? (2) On average, what is the number of classifiers paired up with a noun? (3) What is the number of nouns paired up with a classifier? (4) Which semantic dimensions are particularly relevant to the Chinese classifier system?

In our data, a noun on average pairs up with 2.839 classifiers, and a classifier category generally contains 16 nouns. The most frequent classifier was *zhi1* for animate beings. The noun *di4tu2*, taking 8 classifiers, is the most flexible noun in our corpus. By corpus data we will also talk about the role of *ge0*. Concerning the semantic dimensions, Tai (1994) identified four dimensions manifested in Chinese classifier system: animacy, shape, size, and consistency. And he also found a number of miscellaneous cases that reflect part-whole or metonymic relation. Our investigations show that some classifiers are not highly generalized, such as *zun1* (for statues), *chuang2* (for buildings), *sao4* (for vehicles), etc. Those cases hint at the possibility that some classifier categories operate on low-level classification such as VEHICLE and BUILDING, instead of highly-abstract semantic dimensions.

# Property activation during the Interpretation of Noun-Noun Compounds

Jie Huang

Huazhong University of Science and Technology

**Abstract:** Noun-noun compounding is the most productive way of word formation in many languages. The past two decades have witnessed highly diversified studies in noun-noun compounds from perspectives of linguistics, psychology, computer science and so on (Sweetser 1999; Gagne 2002; Devereux & Costello 2005; Butnariu & Veale 2008; Domnguez 2009). In this paper, we carry out three experiments to examine the process of property activation during the interpretation of noun-noun compounds. The first experiment aims at testifying whether we are more inclined to interpret a novel noun-noun compound with reference to analytic or perceptual properties of the referent. The second experiment tests participants preference for metaphorical or relational association in interpreting novel noun-noun compounds. The third experiment testifies whether cognitive development has any impact on noun-noun compound interpretation. Results from the experiments indicate that cognitive factors, such as encyclopedic knowledge, conceptual similarities and contiguities, cognitive development, influence the interpretation of novel noun-noun compounds.

# Modeling How Naming Experiences Bias Sorting Performance

**Yu-Sheng Hung**

National Cheng Kung University

**Yun Li**

National Cheng Kung University

**Hsueh-Chih Chen**

National Taiwan Normal University

**Jon-Fan Hu**

National Cheng Kung University

**Abstract:** Previous studies assume that language specificity might affect naming patterns, whereas perceptual similarity based sorting might be universal. Study 1 was aimed to examine the hypothesis, but it was found that the correlations of sorting based on perceptual similarity between Chinese and Dutch (or French) are surprisingly lower than previous findings. We argue that perceptual similarity might be also affected by naming experiences. In study 2, we adopted backpropagation neural networks to model the sorting patterns observed in Study 1. During training, the inputs of models were composed of the numeric vectors of names and semantic features. Nevertheless, only semantic features were fed to networks for simulating the sorting results. After training, the simulation outcome of networks showed high correlation with the experimental results. These studies suggest that we should reconsider the involvement of naming experiences for the sorting processes.

Keywords: naming, sorting, perceptual similarity, backpropagation neural networks

# **The Effect of Priming of Individualism/Collectivism on the Miller-Lyer Illusion**

**Yiwon Hyun**

Pusan National University, South Korea

**Donghoon Lee**

Pusan National University, South Korea

**Hyunjung Shin**

Pusan National University, South Korea

**Myeong-ho Sohn**

George Washington University, U.S.A.

**Abstract:** In this study, we tried to find out whether the socio-cultural thinking styles of individualism and collectivism could affect the basic visual perceptual processes such as Miller-Lyer(ML) Illusion. If the collectivistic thinking style induces people to perceive the illusory figure more holistically and to process the relations among the components, collectivism-primed people are more susceptible to the ML illusion. On the other hand, if the individualistic thinking style induces them to perceive the illusory figure more analytically and to process the components separately, individualism-primed people are less susceptible to the illusion. To study the influence of cultural thinking styles on perceptual illusion, one group of Korean students wrote a story about myself for individualism priming and the other group about our group for collectivism priming before the illusion task. As expected, the individualism-primed group showed less ML illusion effect than the collectivism-primed group. In summary, this study suggested that cultural thinking styles could affect the basic visual perceptual processes in a top-down way.

# **How novices get skills without supervisors instructions: through analysis of skills mastery process**

**Jun Ichikawa**

Graduate School of Information Science, Nagoya University, Nagoya, Aichi, Japan

**Yugo Takeuchi**

Department of Information Science, Shizuoka University, Hamamatsu, Shizuoka, Japan

**Abstract:** This study proposes collaborative learning by which anyone can get skills without supervisors instructions. Generally, novices acquire them by being coached. Collaborative learning is defined as a method for studying and solving problems together in a group. In this study, subjects were instructed to get skills as collaborative learning for novices. The mastery process of their skills through the collaborative learning was analyzed by focusing on their speech communication and notes. And, the tacit knowledge to get skills and the process to keep it in mind were formulized from a cognitive point of view. The finding was suggested that a collaborative learning helped novices improve skills and share them, but novices could not figure out whether the outcomes were right or not. Furthermore, it was showed importance of getting skills: clues to know if skills are to decline or not, and ability to adjust opinions by collaborative learning.

# **The relationship between depressive tendency and relative metacomprehension accuracy.**

**Kenji Ikeda**

Nagoya university, Japan Society for Promotion of Science

**Yosuke Hattori**

Tokyo university, Japan Society for Promotion of Science

**Shinji Kitagami**

Nagoya university

**Abstract:** In this study, we investigated the relationship between depressive tendency and relative accuracy of metacomprehension. Many previous studies have focused on negative confidence bias or absolute accuracy of depressive persons (e.g., Fu et al., 2012). However, it has not been examined how depressive tendency affects relative accuracy. In experiment, participants read four expository texts. After reading, participants assigned a comprehension rating to each text and then completed a comprehension test. Finally, participants completed the Beck Depression Inventory (BDI) of Japanese, originally developed by Beck et al (1961). The result showed that there was negative correlation between the score of BDI and relative metacomprehension accuracy. Given that the high score of BDI means serious depressive, this result suggested that depressed persons cannot discriminate the degree of comprehension level between a numbers of texts.

# **A Narratological Mechanism for Generating Macro Structures of Story in an Integrated Narrative Generation System**

**Shohei Imabuchi**

Faculty of Software and Information Science, Graduate School of Iwate Prefectural University, Takizawa,  
Iwate, Japan

**Takashi Ogata**

Faculty of Software and Information Science, Iwate Prefectural University, Takizawa, Iwate, Japan

**Abstract:** This paper proposes a story generation mechanism based on Propp's narratology. Although there are some Propp-based story generation systems, the novel characteristics of our system are combining with a comparatively large scale conceptual dictionary, intending a comprehensive implementation of Propp's theory, and forming a part of our narrative generation system. The central part of the proposed system is a story grammar mechanism that we defined by organizing formally the description of function, which means an action seen from the result, and sub-function, which is our original name and the concrete action of each function. As other modules, the story grammar has a flexible structure which can be replaced by other story patterns and generated stories can be mutually combined. In this paper, we introduce the current version and enumerate future issues.

# A cellular automaton model of ambiguity aversion

**Kenryo Indo**

Kanto Gakuen University

**Abstract:** Daniel Ellsberg (1961) demonstrated that human decision makers tend to avoid unknown probabilities by using a pair of gamble comparisons. The ambiguity aversion has been studied by psychologists, economists, and more recently neuroscientists. For example, non-additive probability can be considered as a descriptive model to explain the ambiguity aversion. However, it lacks a cognitive processing model.

In this paper, a computational approach to modeling cognitive process of choice under ambiguous probability by using cellular automata is proposed. By designing cellular automaton in a torus consisting of "local matches" with the state transition rule by stochastic local  $q$ -majority vote, which is considered as a model of the working memory of decision maker, this paradox can be simulated. In addition, a similar but differently used version of this model can simulate the event-splitting effect which is known to induce, or eliminate, violation of first order stochastic dominance.

# The effects of frameworks and examples in learning how to solve word problems

**Miwa Inuzuka**

Taisho University

**Hirosuke Tanimoto**

Oshimanishi Junior Highschool

**Hiroko Kobayashi**

Japan Society for the Promotion of Science

**Abstract:** The study aimed at finding the way to facilitate students ability to solve proportion word problems. Previous research suggested two different ideas on abstract framework: abstract framework was less effective than examples; abstract representations would be effective in complex problems. Therefore, we focused on the abstractness of framework and the complexity of the problems. We compared problem solving performance of students in three classes with different abstractness in teaching how to solve proportion word problems. In no formula class (N=20), the teacher only showed correct expressions and answers; in abstract formula class (N=24), the teacher showed abstract formula to solve proportion problems; and in situation formula class (N=23), the teacher showed more grounded formula. The results indicated that the students in no formula did better than those in abstract formula condition. The effects of abstract frameworks and examples, and the complexity and transformation of the problems were discussed.

# **Social Projection as a Universal Strategy in Mental State Inference: Cultural Differences in Utilization of Stereotyping**

**Tatsunori Ishii**

Sophia University, Tokyo, Japan

**Masanori Takezawa**

Sophia University, Tokyo, Japan

**Abstract:** It has been argued that people selectively use two strategies, projection and stereotyping, for inferring mental states of the others. Through a series of experiments, Ames (2004) confirmed the hypothesis that, when a target person is perceived to be similar to oneself, people project ones own mental states to the other; when a target is perceived to be dissimilar, stereotype of a group/category the target person belongs to is used for mental state inferences. In this study, we replicated Ames(2004)s experiment in Japan and found that Japanese participants employed the projection unanimously regardless of the perceived similarity to the target person. We interpret this result with Yuki(2003) which argued East Asians perceive a social group as a network of independent people while Americans perceive a group as an entity. Our results thus suggest that stereotyping is a cultural-specific strategy while projection is a universal strategy employed in mental state inference.

# Functions for mutual interaction with the mind reading

**Satoru Ishikawa**

Hokusei Gakuen University, Sapporo, Hokkaido, Japan

**Abstract:** In the interaction with others, we read other's mind or estimate other's inner states, and utilize them for predicting other's behavior and deciding own behavior. Moreover, we utilize them for making someone do as we wished. In this study, we attempt to propose required functions for decision making of own and other's behavior depending on the mind reading processes and suggested mechanisms for realize these functions. Three investigational situations such as advising clothes to a customer, explanation of operating procedures, and misleading the other's belief were conducted and decision making processes of own behavior were analyzed depending on the recorded conversation during these situations or interview on video-playback. These results proposed two required functions: 1) acquisition of other's view of environment and detection of differences between own and other's view, 2) estimation of other's rules for decision making and operating them along with own will.

# **The anger superiority effect in children with and without autism**

**Tomoko Isomura**

Primate Research Institute, Kyoto University

**Hiroyasu Ito**

Primate Research Institute, Kyoto University

**Shino Ogawa**

Primate Research Institute, Kyoto University

**Miwa Fukushima**

Research Center for Advanced Science and Technology, Tokyo University

**Masahiro Shibasaki**

Primate Research Institute, Kyoto University

**Nobuo Masataka**

Primate Research Institute, Kyoto University

**Abstract:** In the face recognition research, it is well known that angry faces are detected more quickly than happy or neutral faces because of the attention-getting property provided with such threatening stimuli. This rapid processing to the threat, usually referred to as "the anger superiority effect", is thought to be automatic and inherent. Here, we examined the anger superiority effect in children with and without autism spectrum disorders (ASD) using visual search paradigm. Results revealed that the effect of emotion is correlated with age in children with ASD, but not in typically developing children. In addition, children with ASD under 9 years did not show the anger superiority effect whereas it was confirmed in typically developing children of the same age and even in younger ages. Children with ASD would be delayed for acquisition of those cognitive effects, which might be related to their delay of acquisition of variable social skills.

# **Culture, perception, and artistic visualisation: A comparative study of children's drawings in three Siberian cultural groups**

**Kirill Istomin**

Max Planck Institute for Social Anthropology, Halle (Saale), Germany

**Jaroslava Bagdasarova,**

Max Planck Institute for Social Anthropology

**Patrick Heady**

Max Planck Institute for Social Anthropology

**Abstract:** In a study of three indigenous and non-indigenous cultural groups in Northwestern and Northeastern Siberia, framed-line tests and a landscape drawing task were used to examine the hypotheses that test-based assessments of context-sensitivity and independence are correlated with the amount of contextual information contained in drawings, and with the order in which the focal and background objects are drawn. The results supported these hypotheses, and inspection of the regression relationships suggested that the inter-group variations in test-performance were likely to result from differences in the attention accorded to contextual information, as revealed by the drawings. Social and environmental explanations for the group-differences in contexts ensitivity are also discussed. The conclusions support the argument that cultural differences in artistic styles and perceptual tests reflect the same underlying perceptual tendencies, and are consistent with the argument that these tendencies reflect corresponding differences in patterns of social and environmental interaction.

# How do children with autism solve logic puzzle?

**Hiroyasu Ito**

Primate Research Institute, Inuyama, Aichi, Japan

**Nobuo Masataka**

Primate Research Institute, Inuyama, Aichi, Japan

**Abstract:** In this time, we examined that how children with autism solve logic puzzle. Seventeen school age children with autism and 17 age- and ability-matched typical children took part in the experiments. Two toys (a doll of robot and electric switch toy) were set on an architectural replica of house, and these were on a white styrofoam board. Children were instructed to search arbitrary rule that is relation between the position of robot and an on/off of electric switch toy. Children with autism solve the rule of logical AND and XOR problem (exclusive or problem) as good as typical children, but it was more difficult for children with autism to solve the rule of XOR in the big house replica on which there are many replicas of furniture than typical children. There were so many toys that Children with autism lost track of conceptualizing the pattern.

# Effects of Base Rates and Likelihoods on Intuitive Probabilistic Judgments

Tomoko Itoh

Japan Society for the Promotion of Science / Waseda University

**Abstract:** Sixty university students solved four intuitive probability problems in which two base rates (the probabilities that people in a country are genetically predisposed to a disease) and two likelihoods (the probabilities that people who are genetically predisposed to the disease will actually develop it even if they are vaccinated) were provided. Participants made judgments on whether they would get vaccinated on the basis of the information. The number of participants who responded that they would get vaccinated was significantly different across problems. More participants responded that they would get vaccinated when the base rate was 800 out of 1000 than when it was 1 out of 1000. If the base rates were the same, more participants responded that they would get vaccinated when the likelihood was 15% than when it was 75%. These results suggest that people make intuitive probabilistic judgments on the basis of both base rates and likelihoods.

# Representational Form and Metaphorical Word Use

**Anja Jamrozik**

Northwestern University

**Micah Goldwater**

Northwestern University

**Eyal Sagi**

Northwestern University

**Dedre Gentner**

Northwestern University

**Abstract:** How does semantic representation influence the likelihood that a word will be used metaphorically? We explore whether words whose meanings are defined by relations among entities (e.g., marriage, forget), are more likely to be used metaphorically than words whose meanings are defined by features of entities (e.g., bird). Verbs are generally more relational than nouns (Gentner, 1981). Relationality can also distinguish different kinds of nouns: specifically, relational nouns (e.g., marriage) vs. entity nouns (e.g., bird) (Gentner & Kurtz, 2005; Goldwater, Markman, & Stilwell, 2011; Markman & Stilwell, 2001). Prior studies have shown that the meanings of relational words are more mutable across contexts than those of entity words (Gentner & France, 1988; Asmuth & Gentner, under review). Extending this work, we find that uses of relational words (both verbs and relational nouns) tend to be more metaphorical than uses of entity nouns in natural language corpora.

# Interaction between ability and use of scaffold in EFL vocabulary learning system

**Felix Jimenez**

Chukyo University, Toyota, Aichi Pref, Japan

**Masayoshi Kanoh**

Chukyo University, Toyota, Aichi Pref, Japan

**Abstract:** This study clarified self-regulated learning processes in EFL in order to propose a more adaptive learning system. We developed an English vocabulary learning system for Japanese. It presented each word in an example sentence and the Japanese translation of the sentence except for the target word upon user request. We sought to examine how learners use this system as a scaffold. Five college students of lower and intermediate ability used the system for six weeks and took exams. We found that the intermediate-ability group learned more vocabulary than the lower-ability group, even when compared to similar-level students using another system that provided only words and translation. Process analyses revealed that the lower-ability group depended on help all through the period, while the intermediate-ability group decreased its use gradually as if to check their learnability. This suggests that the future system have both scaffolding and fading-out functions adaptable to learning states.

# Qualitative differences in sequence planning with everyday objects in traumatic brain injured individuals

**Arianne Johnson**

University of California, Santa Barbara

**Scott Grafton**

University of California, Santa Barbara

**Abstract:** The present study aimed to characterize what errors in sequential tasks that traumatic brain injury (TBI) subjects make relative to controls. Subjects (8 healthy controls, 6 TBI subjects) completed a computerized grocery bagging task on a touchscreen that required bagging items according to object properties. Relative to controls, TBI subjects produced marginally more errors overall. However, the TBI group had different error profiles than the control group. Specifically, on trials that required a nested rule (i.e. clumping items according to temperature and ordering these same items in terms of weight), the TBI group had more than twice as many errors as controls. This performance deficit is specific to nested rules as the TBI error rates did not differ relative to controls on trials that required multiple rules that were not nested. These findings suggest that planning deficits from TBI cannot simply be due to increased memory load of number of rules but instead is more specific to sequence planning.

# Differential Effects of the Cultural Orientation Dimensions on Global Precedence

**Mijung Joo**

Pusan National University

**Hyunmin Kang**

Pusan National University

**Hyunjung Shin**

Pusan National University

**Jaesik Lee**

Pusan National University

**Abstract:** This study investigated the differential effects of individualism-collectivism dimension (ICD) and horizontal-vertical dimension (HVD) in cultural orientation of individuals in the same cultural background on global precedence. The participants were classified into ICD and HVD groups, and asked to respond to compound stimuli which were varied by stimuli types (figure/letter) and stimulus-stimulus (S-S) congruence. Differences in global precedence were compared. The results showed the followings. First, although global precedence was larger in the compound figure than in the compound letter, and larger in the S-S incongruent condition than the congruent condition, none of cultural orientation dimensions made any difference. Second, ICD and HVD affected global precedence independently. Third, a significant interaction effect between HVD and S-S congruence was found, but there was no interaction between ICD and S-S congruence. These results indicated HVD rather than ICD can be a more valid dimension to compare the effect of individual differences in cultural orientation on global precedence.

# **Hierarchical Category Structures Facilitate Acquisition of Probabilistic Relational Categories.**

**Wookyoung Jung**

University of Illinois at Urbana-Champaign

**John Hummel**

University of Illinois at Urbana-Champaign

**Abstract:** Kittur et al. (2004, 2006) and Jung & Hummel (2009, 2011) showed that people have great difficulty learning relation-based categories with a probabilistic (i.e., family resemblance) structure, in which no single relation is shared by all members of a category. Yet acquisition of such categories is not strictly impossible: In all these studies, roughly half the subjects eventually reached criterion. What are these subjects doing that the other half are not? We hypothesized that successful subjects were those who divided the nominal categories into two or more sub-categories, each of which individually has a deterministic structure. We report an experiment testing and supporting this hypothesis: Explicitly presenting subjects with hierarchical (category and sub-category) structures facilitated the acquisition of otherwise probabilistic relational categories.

# Dynamic Effects of Perceptual and Categorical Similarity on Recognition Memory

**George Kachergis**

Indiana University

**Gregory Cox**

Indiana University

**Richard Shiffrin**

Indiana University

**Abstract:** Memory is sensitive to several aspects of its contents, including item similarity (Tulving, 1981) and value (Kachergis, Recchia, & Shiffrin, 2011). For the present study, we developed and scaled a new class of blob-shaped stimuli in order to manipulate item similarity. In two experiments, participants studied blob-point value pairs, with categories defined by valence (positive/negative point values) and by perceptual similarity of the stimuli. Using a dynamic 2AFC decision-making paradigm with a response deadline, we recorded response trajectories for different foil types (e.g., similar to the target, or unique). We find similarity effects in recognition memory and semi-paradoxical category size effects in accord with Tulving (1981). Interpretation of the accuracy effects is enhanced by examining the shape and timing of response trajectories, allowing us to measure phenomena such as decision reversals. Finally, we present a general Gaussian process regression framework to analyze such continuous response data (Cox, Kachergis, & Shiffrin, submitted).

# Asymmetry of McGurk Effect Depending on the Orientation of Faces

**Masayo Kajimura**

Kyoto University

**Hiroshi Ashida**

Kyoto University

**Abstract:** We examined whether the McGurk effect depends on speakers facial orientation. Speakers vocalizing scenes of, /ba/, /da/, and /ga/ were videotaped in two angles from the left and the right. A voice and a face were congruently or incongruently combined. The experimental stimuli were edited to produce normal and mirror-inverted versions of each audio-visual pair. Participants were asked to report the syllable as they heard by free description. The result replicated the McGurk effect. The error rates were higher for the mirror-inverted right-looking faces (seen as left-looking) than for the mirror-inverted left-looking faces (seen as right-looking). And the error rates were higher for the mirror-inverted right-looking faces (seen as left-looking) than for the normal right-looking faces. These results suggest that left-looking faces enhance the McGurk effect, while differences in physical movements of the left and right sides of speakers mouth could be also relevant.

# **An Optimality Theoretical Analysis of Urge Interactions in Toda's (1982) Emotional Fungus-Eater Robots**

**Yasuo Kaneko**

Kushiro Public University

**Abstract:** Toda's (1982) Urge Theory of Emotions (TUTE) is a deductive theory of emotion and cognition. The TUTE is deductive in that one of thrusts of the TUTE is a detailed analysis of individual emotions as necessary softwares of robots named Fungus-Eaters working on an imaginary planet. The Urges are built-in motivational subroutines for making decisions and executing action plans in order to solve survival problems in a wild environment. The urges are supposed to interact in a situation but not to be absolute but violable. However, the nature of the urge interactions remains to be clarified. The purpose of this study is to apply Optimality Theory (Prince & Smolensky, 2004) to an analysis of the urge interactions because OT is a theory of interactions of violable constraints. The application makes the urge interactions more visible by means of tableau and accessible for scrutiny than in the TUTE.

# **A signal detection analysis of the effects of repeated context on visual search**

**Ryan Kasper**

University of California Santa Barbara, Santa Barbara, California, United States

**Miguel Eckstein**

University of California Santa Barbara, Santa Barbara, California, United States

**Barry Giesbrecht**

University of California Santa Barbara, Santa Barbara, California, United States

**Abstract:** When searching for a target in a scene, previously learned spatial context can facilitate response times (Chun & Jiang, 1998). However, it has been debated whether this is driven by attentional guidance (Chun, 2000; Geyer et al., 2010) or response selection processes (Kunar et al., 2007; Kunar & Wolfe, 2011). To address this issue, 18 subjects performed a visual search task in which (a) the spatial configuration was either repeated or novel, and (b) the target was either present or absent. The present/absent manipulation permitted signal detection computations to decouple perceptual sensitivity ( $d$ ) and response bias ( $\beta$ ). Average RT was faster ( $p < 0.01$ ) and  $d$  was increased ( $p < 0.03$ ) for repeated displays, but there was no effect on ( $p > 0.45$ ). These results suggest that early perceptual processes, as opposed to response processes, may provide a greater contribution to the benefits of repeated context in visual search.

# Cultural variations in authority management in interaction

Yasuhiro Katagiri

Future University Hakodate

**Abstract:** Status difference, such as in seniority, wealth or social roles, plays an important role in human joint decision making situations. The degree of effectiveness of authority brought about by status difference naturally varies across different cultural groups. But, the way in which authority manifests itself in joint decision making situations also changes in different cultural groups. We have been studying cultural variations in dialogue interaction styles through the examination of Mister O corpus, a task-oriented dialogue corpus which has been collected over several languages, including Japanese, English and Arabic. We identified a contrastive manifestations of authority in Mister O dialogues, which can be characterized in terms of different emphasis on competence and deference. We discuss possible evolutionary underpinnings of the diversity of interaction style manifestations, based on the notion of multi-level selection and tribal social instinct hypothesis.

# Differences in emotional bias effect on working memory in elderly.

**Maya Katsuhara**

Kyoto university

**Mariko Osaka**

Osaka university

**Naoyuki Osaka**

Kyoto university

**Abstract:** This study investigated age-related differences in the inhibition mechanism for negative emotional information and in the facilitation mechanism for positive emotional information in working memory. Thirty-six older and thirty-six younger adults performed three RSTs: the neutral, negative, and positive emotional conditions. For each RST condition, all target words were neutral words, while the sentences themselves corresponded to the conditions. In older adults, the percentage of correct responses in the negative condition was worse than that of the neutral condition. Conversely, in younger adults, there was no significant difference between the neutral and negative conditions. In contrast, performance in the positive condition was better than the neutral condition for both age groups. These results suggest that the inhibition of negative information comes at a greater cost to older adults compared to younger adults, but the benefit of the positive information is the same in both age groups.

# **Mental rotation of pictured body stimuli: Involvement of visual representation of the stimuli**

**Tsubasa Kawasaki**

Tokyo Metropolitan University

**Takahiro Higuchi**

Tokyo Metropolitan University

**Abstract:** The present study investigated whether the time required for recognizing rotated body stimuli was matched strictly with the magnitude of correspondence regarding rotation angles between the stimulus and the body. Twelve young adults sat in front the computer monitor while their body was facing to it (no body rotation) or was rotating to the side by 90 degrees. They classified a body stimulus (hand or foot) presented with one of four orientations (0, 90, 180, -90) according to their laterality. The result showed that the time required for the classification was generally matched with the magnitude of correspondence regarding the rotation angles. However, the classification time was the longest for the 180-deg rotated stimulus even while the body was rotated by 90 degrees, demonstrating that the magnitude of rotation of the body stimuli itself affected the MR. It is likely that visual representation of the stimuli, as well as the body schema, is involved in the MR.

# Extracting the Musical Schema from Traditional Japanese, Chinese and German Folk Songs

Akihiro Kawase

Tokyo Institute of Technology

**Abstract:** In this study, we extract the pitch transition patterns from traditional Japanese, Chinese and German folk songs, and examine the characteristics of their respective schema. We sample 1,794 works from Nihon Min-yo Taikan for Japanese folk songs, 1,984 and 2,286 works from a website providing virtual musical scores for both Chinese and German folk songs, respectively. Our main method of extracting pitch transition patterns is to fit variable-length Markov chains (VLMCs) from musical data. A variable-length Markov chain model is a Markovian process having a sparse memory structure with some states that closely cohere. The structure can be characterized by a parsimonious number of transition probabilities for stationary categorical time series. The results indicate that the minimal structures of Japanese folk songs tend to create a longer schema than other two folk songs, while the minimal structures of both Chinese and German folk songs tend to create a shorter schema.

# **Implicit learning on the order of the visual stimuli under interocular suppression**

**Kaede Kido**

Osaka prefecture university

**Shogo Makioka**

Osaka prefecture university

**Abstract:** We investigated whether learning on the order of the visual stimuli occurs under interocular suppression. In learning phase, low contrast characters were presented sequentially to one of the eyes. Conscious perception of the characters was suppressed by flash streams presented to the other eye (continuous flash suppression). The character streams consisted of quadruplets of fixed order characters, and the order of the quadruplets was randomized. The characters were selected from Yi script that was new to the subjects. In testing phase, the quadruplets were presented to the both eyes, and the subjects hit the key as soon as the target character appeared. If the subjects respond faster when the position of the target was later in the quadruplets, it is likely that they had learned the order of the stimuli. Preliminary data suggests that the learning on the order of novel visual stimuli occurred under interocular suppression.

# Hierarchical Slow-Feature Models of Gesture Conversation

**Jiseob Kim**

Seoul National University, Seoul, Korea, Republic of

**Sooyong Jang**

Seoul National University, Seoul, Korea, Republic of

**Eun-Sol Kim**

Seoul National University, Seoul, Korea, Republic of

**Byoung-Tak Zhang**

Seoul National University, Seoul, Korea, Republic of

**Abstract:** How do humans interact with each other using gestures? How do they catch the semantics of gestures to predict or react to them? We explore hierarchical slow-feature models to obtain the high-level semantics in conducting gesture conversations. We adopt the hypernetwork model as a basic component to learn the elementary semantics of gestures, and combine two hypernetworks with an added upper-layer of slow features to learn the temporal transition of semantics. This hierarchical slow-feature model abstracts the low-level features of joint angles to the slowly-changing high-level features which represent higher-level semantics of the gestures. This model also learns the probability of the partners next gesture given the gesture of one person at a semantic level. We experimented with the Kinect motion capture device to record the gestures of two subjects in gesture conversation scenarios. The human gesture data was used to train the hierarchical slow-feature model to predict the gesture conversations. The trained model is then transferred to the Darwin humanoid robot. We compare the human behaviors and the robot behaviors that learned from the human gestures.

# **Is this right? or Is that wrong?: Evidence from Dynamic Eye-Hand Movement in Decision Making**

**Eun-Sol Kim**

Seoul National University, Seoul, Korea, Republic of

**Jiseob Kim**

Seoul National University, Seoul, Korea, Republic of

**Thies Pfeiffer**

Bielefeld University

**Ipke Wachsmuth**

Bielefeld University

**Byoung-Tak Zhang**

Seoul National University, Seoul, Korea, Republic of

**Abstract:** Eye tracking and hand motion (or mouse) tracking are complementary techniques to study the dynamics underlying human cognition. Eye tracking provides information about attention, reasoning, mental imagery, but figuring out the dynamics of cognition is hard. On the other hand, hand movement reveals the hidden states of high-level cognition as a continuous trajectory, but the detailed process is difficult to infer. Here, we use both eye and hand tracking while the subject watches a video drama and plays a multimodal memory game (MMG), a memory recall task designed to investigate the mechanism of recalling the contents of dramas. Our experimental results show that eye tracking and mouse tracking provide complementary information on cognitive processes. In particular, we found that, when humans make difficult decisions, they tend to ask 'Is the distractor wrong?', rather than 'Is the decision right?'.

# State Anxiety and the Processing of Covariation Information in Causal Reasoning

**Young Il Kim**

Ajou University

**Kyung Il Kim**

Ajou University

**Abstract:** The phenomena of conditionalization and discounting have been studied as reflection of attention to multiple potential causes in causal reasoning. And it has been observed that individual-difference factors significantly influence causal reasoning. Specifically, previous studies showed that sociality anxiety related factors such as self-construal influence levels of conditionalization and discounting. In this study, we further specified the relationship between anxiety and the two mechanisms in causal reasoning. We manipulated participants levels of state anxiety and found that participants with a relatively greater state anxiety showed a greater propensity to discount their judgment on an alternative cause. But this pattern was not observed in conditionalization between participants with two different levels (high vs. low) of state anxiety. First, these results suggest that conditionalization and discounting are independent to each other, further supporting previous studies. Second, we propose that different individual-difference factors specifically influence the two mechanisms in causal reasoning.

# **Cultural priming and the scene perception**

**Bia Kim**

Pusan National University

**Yoonkyoung Lee**

Pusan National University

**Donghoon Lee**

Pusan National University

**Goeun Lee**

Pusan National University

**HyunJung Shin**

Pusan National University

**Abstract:** A newly constructed 'cultural priming story writing task' was used to examine the hypothesis that priming of individualism leads to pay attention to the targets more than the grounds, whereas priming of collectivism leads to equally distribute attention to the relation between the targets and the grounds as well as the targets in the scene perception. In addition, focusing on the contradictory results of previous studies, we investigated the effect of instruction: In Experiment 1, participants were instructed to rate the preference of the scenes, whereas they were informed the recognition test beforehand in Experiment 2. The results supported the hypothesis: The collectivism-primed participants pay more attention to the figure-ground relevance information than the individualism-primed ones. However, the difference was disappeared in Experiment 2. It was suggested that intention to memorize scenes can affect the attentional allocation to the targets and the grounds regardless of the cultural dispositions.

# **Complex Network Analysis of Social Relationships and Personality from TV Drama Dialogues**

**Joon Shik Kim**

Seoul National University

**Chung-Yeon Lee**

Seoul National University

**Minsu Zhang**

Sangmoon High School

**Jun-Hee Nam**

Sangmoon High School

**Abstract:** Dialogues are linguistic interactions between people and can provide hints on social relationship and personality. We aim to analyze the social relationships of the characters in TV dramas based on dialogues. In addition to knowing just who talks to whom, the analysis of dialogue content gives more detailed information on the types of interaction, e.g. asking or informing, and the emotional status. We use complex network measures, such as path lengths, geodesics, cluster coefficient, and centrality, to analyze the structural and functional properties of the dialogue network. Among others, we found the betweenness centrality measure informative for identifying the social relationships since this assesses the importance of a node in a complex network in which small worldness is inherent. Analyzing the complete corpus of TV drama Friends aired for 10 years, we discovered the connector nodes which are essentially the social equivalent of a hub of computer network. Complexity measures of the dialogue network also help characterize the personality of the main characters in the dramas we studied. The text-based analysis of the present work can be extended to incorporate the sound modality to capture further information on the characters and their interactions.

# A Neuroethological Approach to Robotics

**DaeEun Kim**

Yonsei University, Seoul, South Korea

**Abstract:** Many animal behaviors provide a clue to animal intelligence. The underlying neural mechanism is still unsolved in many cases, but the study stimulates relevant studies in the field of artificial intelligence and robotics. Robotic researchers have interest in how sensory system is connected to motor actions and what kind of learning mechanism or what coordination in the sensorimotor mapping is helpful to the efficient operation of machines or their parts. In the field of artificial intelligence, researchers try to find optimal strategies with the acquired environmental information. A neuroethological approach to animal behaviors, which handles the interaction of neural circuitry to explain the behavioral concept, can find many clues of animal cognition. It also provides a systematic and integrative foundation of intelligence needed in robotics and artificial intelligence, which might lead to intelligent systems or robots.

# The effectiveness of English teaching integration model based on task-based approach

Eun sook Kim

Pusan National University

**Abstract:** Task-based activities have become very popular recently in both stand-alone and content-based language classes. Also, They are taken into account to improve students responsibility and sociality in English learning. This study tries to devise an integration of English teaching model that integrate reading, writing, speaking and culture, based on task-based learning approach, and investigate the improvement of interest and confidence about English productive competency like writing and speaking, which has significantly risen ( $t=0.04$ ,  $p<.05$ ) in pre- or post- application of the model. Approximately 55 percent of the students responded that the model was effective for the organization abilities of materials and the confidence about essays and presentations. There are no meaningful differences between the emotional aspects and the cognitive aspects( $t=1.61$   $p.05$ ).

# Nominal Number and Semantics of Common Nouns in Numeral Classifier Languages

**Jecheon Kim**

Hankuk University of Foreign Studies, Seoul, Korea

**Abstract:** The present study argues against the predominant view in the literature that the default semantic denotation of common nouns in numeral classifier languages, i.e., table, is similar to the denotation of the mass nouns in English, i.e., furniture. Based on this mass noun view, many linguists argue that there is no count-mass distinction in numeral classifier languages.

I show that the mass noun view based on simple morpho-syntactic analogies between English and numeral classifier languages has a number of problems both in theory and in the interpretation of the data. I provide evidence for the existence of a count-mass distinction in numeral classifier languages from various areas of grammar based on the Korean data and supporting evidence from the researches in other disciplines.

My study will be able to contribute to the renewed and correct understanding on the nature of common noun semantics of the numeral classifier languages.

# **Automaticity in Motor Learning: Evidence from Visuo-motor Tracking Performance and Pupil Dilation**

**Satoshi Kobori**

Ryukoku University

**Yosuke Abe**

Ryukoku University

**Shogo Nakazono**

Ryukoku University

**Abstract:** Motor learning has traditionally been associated with the concept of automaticity. Automaticity refers to the reduction of the cognitive effort required to perform a motor task, as learning progresses. However, there is little detailed consensus in the literature on what the process of automatization actually involves. We measured tracking performance in two groups of participants while either the target or the manual cursor was suppressed for a brief period during each trial. Subjects learned to maintain accurate tracking through periods of target or cursor suppression. We have used this approach to investigate the internal models used during tracking, and their updating during motor learning. We have simultaneously measured tracking performance and pupil dilation as a measure of cognitive load. The results showed that pupil diameter decreases with learning process of tracking performance. Decrease of pupil diameter suggests that automatization is linked specifically to the learning of internal models.

# Self-Organization of Policy by Symmetric Reasoning and its Application to Reinforcement Learning

**Yu Kohno**

Tokyo Denki University

**Tatsuji Takahashi**

Tokyo Denki University

**Abstract:** The real limitations to our cognition and our locality lead to the exploration-exploitation dilemma and hence the tradeoff between speed and accuracy. Considering that all creatures especially animals efficiently deal with the tradeoff, it is natural to suppose we can intuitively handle the dilemma. We adopt the loosely symmetric (LS) formula as a toy model of our intuitive judgment. LS, a kind of biased conditional probability, is known to precisely describe our probability judgment and to go beyond the ordinary tradeoff of speed and accuracy in two-armed bandit problems. In this study, we give analyses of LS in relation to its information theoretical and logical-probabilistic nature. Along with the analyses, we extend LS from a conditional probability to a general value function. The efficacy of LS in decision-making under risk and reinforcement learning is proven by experiments and simulations.

# Study on Facilitation of Problem Posing by Learning Examples through Reproduction

**Kazuaki Kojima**

Waseda University

**Kazuhisa Miwa**

Nagoya University

**Tatsunori Matsui**

Waseda University

**Abstract:** In general education, learning of production tasks is important but difficult due to it requires heavy cognitive activities such as generation of ideas and synthesis of structures. We proposed a method to facilitate a production task of mathematical problem posing through learning by reproducing examples. In the proposed method, learners learn essential ideas by reproducing examples based on process information indicating how to compose them. We then conducted an experimental investigation where undergraduate students posed their own problems after learning an example by reproducing or solving it. Our previous study had confirmed that undergraduate students without learning of any examples posed many problems that had simple and inappropriate solution structures. In this study, undergraduate students who learned by reproducing the example posed many complex problems, whereas those who learned by solving it didn't do. This proved that learning of ideas for a production task is more effective when it's done through a productive activity.

# Egocentric and allocentric frame of reference in virtual maze navigation

**Takatsugu Kojima**

Shiga University of Medical Science

**Abstract:** This study examines how a representation of an egocentric orientation influences selecting an allocentric frame of reference when we guide someone through a virtual maze constructed by three-dimensional computer graphics. In two experiments, participants guided a human-like agent through a virtual maze. They were instructed to use an allocentric frame of reference (an agent-centered frame of reference) to guide the agent through a maze in Experiment 1. Additionally, they were instructed to represent their own orientations during navigation and to answer their own orientations at a maze's goal in Experiment 2. We controlled experimentally sizes of mazes and analyzed participants' patterns and reaction times of selecting a direction of movement for the agent in the two experiments. The results showed that a representation of an egocentric orientation influenced selecting an allocentric frame of reference in maze navigation depending on a size of a maze.

# Consciousness and the language faculty: awareness, qualia and natural language using agents

Piotr Konderak

Maria Curie-Skłodowska University, Lublin, Poland

**Abstract:** I would like to begin with the role of language in settling the problem of consciousness. Some expressions of our everyday language (entering the consciousness, accessible to consciousness consciousness reads) suggest the wrong idea of the phenomenon, namely consciousness as something external in relation to mental states. My first claim is that mental states are conscious due to some internal property.

Accepting Chalmers' distinction between psychological and phenomenal consciousness I will analyse functioning of a natural language processing agent of the SNePS system and indicate hypothesized places and roles for psychological consciousness.

Although explaining the language faculty requires taking into account only awareness, language is also inseparably connected with qualia. Answering the question why qualia accompany some (and what) aspects of language, I will speculate that qualia (regardless their experiential character) have a function similar to Damasio's somatic marker: they allow a kind of pre-processing, triggering psychological mechanisms.

# Three co-creation stages in formation of symbol communication systems

**Takeshi Konno**

Japan Advanced Institute of Science and Technology

**Junya Morita**

Japan Advanced Institute of Science and Technology

**Akihito Kishino**

Japan Advanced Institute of Science and Technology

**Takashi Hashimoto**

Japan Advanced Institute of Science and Technology

**Jiro Okuda**

Kyoto Sangyo University

**Maki Suzuki**

Kyoto Sangyo University

**Abstract:** In Konno et al.'s (in press) experiment of co-creation of artificial language, it has been confirmed that a formation pattern had three stages: the establishment of conventional behavior, symbol system and division of roles using turn-taking. However, forty percent of participants failed the formation. We consider that a cause of the failure lies in difficulty of separation among the three stages which demand learning at different levels. Thus we designed three tasks in order to separate the three stages explicitly. Consequently, all twelve pairs completed the co-creation task, and the differences between two experiment's final scores were significant. This indicates that the order of establishment would lead to form an effective symbol communication system. We suggest that the order has an effect of scaffolding the formation. Finally, we will discuss whether the order has an effect of starting small (Elman, 1993) for the learning at the different levels.

# **Theory of Mind network encodes how you know what you know in blind and sighted adults**

**Jorie Koster-Hale**

Massachusetts Institute of Technology

**Rebecca Saxe**

Massachusetts Institute of Technology

**Marina Bedny**

Massachusetts Institute of Technology

**Abstract:** Theory of Mind (ToM) is the ability to reason about mental experiences such as beliefs and desires. ToM depends on a specific network of brain regions, including the right temporo-parietal junction (RTPJ). We investigated whether these brain regions distinguish between others' mental states experienced through seeing vs hearing ('Sarah saw that', vs 'Sarah heard that'), using multivoxel pattern analyses (MVPA). We find that the spatial pattern in the RTPJ distinguishes stories about mental states experienced through hearing vs. seeing (i.e. source) but not other salient distinctions, such as the positive vs. negative affective valence of the mental state. To investigate effects of first-person experience on these representations, we repeated the experiment in congenitally blind participants. Again, MVPA in the RTPJ distinguished source but not valence. We conclude that 1) the source information of someone else's mental state is coded in ToM brain regions and is a feature of ToM, and 2) these ToM representations of perceptual source are not based on first-person perceptual experiences.

# **A joint ideomotor effect increases the inter-brain oscillation between two people engaged in a Japanese Ouija board Kokkuri-san.**

**Kenta Kubo**

Japan Science and Technology Agency

**Kentaro Katahira**

Japan Science and Technology Agency

**Kazuo Okanoya**

University of Tokyo

**Masato Okada**

University of Tokyo

**Nobuyuki Kawai**

Nagoya University

**Abstract:** We investigated the inter-brain activity coherence recorded by an EEG between two participants when playing at Kokkuri-san, a Japanese Ouija board. The Ouija aboard, known as a spirit key board or talking board, is a flat board, marked with the letters of the alphabet, numbers, or words (yes or no). While playing at the Ouija board, two or more participants place their fingers on the planchette, and it moves about the board and spells out words. The Ouijas actions are generally considered to be due to the ideomotor effect. The EEG results showed that inter-brain activity coherence was observed more dominant in the temporo-parietal junction when the participants shared the goal (in this case, yes or no) than when they did not. These results suggest that shared ideomotor effects produce brain oscillations in the cortical area, which are used for mentalizing.

# **A Framework of Sentence Generation Mechanism for a Narrative Generation System**

**Shinya Kumagai**

Iwate Prefectural University, Iwate, Japan

**Sou Funakoshi**

Iwate Prefectural University, Iwate, Japan

**Junpei Ono**

Iwate Prefectural University, Iwate, Japan

**Taisuke Akimoto**

Iwate Prefectural University, Iwate, Japan

**Takashi Ogata**

Iwate prefectural university, Iwate, Japan

**Abstract:** For language representation in our narrative generation system, we have used a simple sentence generation mechanism. This paper discuss the more comprehensive framework. The approach contains linguistic aspect and strategic or controlling aspect. For the former, we developed programs for word order transformation, verb conjugation operation, complex sentence generation, and letter notation selection. The last function uses a language dictionary for nouns and verbs connected to a conceptual dictionary for noun and verb concepts. For the latter, we use the category of voice in Genettes narrative discourse theory, which means a concept to define the feature and relationship of narrator and narratee to decide the strategy and direction of discourse and language generation. In this paper, based on the developed sentence generation programs, we propose a comprehensive framework consisting of the definition of narrator & narratee, strategic decision rules, and concrete sentence operation modules.

# **An on-line model of quantifiers interpretation in Japanese**

**Takeo Kurafuji**

Ritsumeikan University

**Masakatsu Inoue**

Mukogawa Women's University

**Michinao Matsui**

Osaka Health Science University

**Abstract:** The present project investigates apparently paradoxical phenomena concerning quantificational expressions in Japanese sentence processing as follows. Given structurally ambiguous sentences, (i) when both the nominative and the accusative NPs are bare nouns (nouns without quantifier, interpreted existentially), the garden path (GP) effect is observed, while (ii) when either one of the NPs has a quantifier such as *\_subeteno\_* 'all/every', the GP effect reduces, but (iii) when both are quantified, the GP effect reemerges. The question is: if the existence of one quantifier reduces the GP effect, why not two? We argue that in (ii) the scope interaction of the quantifier and the bare noun is computed, which retards the syntactic processing, resulting in the low GP effect. On the other hand, in (iii), because of its complexity, the scope interaction is not computed, and those quantifiers are treated as non-quantificational, group objects.

# Beauty and Cuteness in Peripheral Vision

**Kana Kuraguchi**

Kyoto Univ., Kyoto, Kyoto, Japan

**Hiroshi Ashida**

Kyoto Univ., Kyoto, Kyoto, Japan

**Abstract:** Previous research suggests that attractiveness is not only detectable in the central visual field but also in the periphery. In Japan, visual attractiveness of people is often described in terms of beauty and cuteness (kawaii). We examined how perception of facial attractiveness in those two aspects can be different in peripheral vision where special resolution is deteriorated. Pairs of female face images were presented at several eccentricities, and participants judged which was better in terms of beauty or cuteness. The results showed that participants were able to judge both beauty and cuteness in the periphery. The discrimination performance, however, differed; beauty was more detectable in the periphery than in the parafovea, while cuteness was more detectable in the parafovea. This result suggests that detection of beauty might be ecologically more important for humans. Moreover, there were some gender differences, which may reflect different meaning of facial attractiveness for each gender.

# **Motion-related brain activity enhanced by motion representation during metaphor understanding**

**Naoko Kuriyama**

Tokyo Institute of Technology

**Asuka Terai**

Tokyo Institute of Technology

**Takashi Kusumi**

Kyoto University

**Masanori Nakagawa**

Tokyo Institute of Technology

**Kimihiko Yamagishi**

Tokyo Institute of Technology

**Koji Jimura**

Tokyo Institute of Technology

**Abstract:** Previous neuroimaging studies have suggested the involvement of motor-related brain regions during semantic processing of action-related idioms and fictive motion sentences. However, it remains unclear if such regions are also involved in understanding of metaphorical expressions. Because metaphor understanding requires abstract semantic manipulations and elaborated feature mapping, one possibility remains that it involves more semantic processing implicated in fronto-temporal regions. On the other hand, due to the conspicuous nature of active items, it may enhance representation of motion and actions, resulting in increased activations in motor-related brain regions. The current fMRI study tested these hypotheses by measuring brain activity while participants made semantic judgments about metaphor sentences involving action and motion. The motion metaphor condition, relative to the motor-related but literal condition, showed prominent brain activity in a fronto-motor region near BA 4. This result suggests that understanding of motion-related metaphor induces direct representation of action and motion.

# **The influence of redundant and idiosyncratic attributes on coherence within a category and contrast between categories**

**Ikuko Kyoya**

Ritsumeikan University

**Masaomi Oda**

Ritsumeikan University

**Abstract:** Many studies on categorization assume that not only coherence within a category but also contrast between categories is important for categorization. This study used line drawings of fictional insects to examine how redundant and idiosyncratic attributes influence categorization. In this study, these attributes were color attributes (brown or blue) that were added to only one instance for each of two categories during category learning and were mutually different between categories. After category learning, a transfer test involving categorization judgments and confidence ratings for those judgments was conducted. The results suggested that the idiosyncratic color of the own category did not help participants to categorize instances into this category, but the idiosyncratic color of the other category deterred participants from categorizing instances into the own category. These results reveal that categorization involves a complex process of drawing contrasts between categories.

# **Assessment and refinement of an intelligent tutor for complex decision making**

**Daniel Lafond**

Defence R&D Canada

**Sebastien Tremblay**

Universite Laval

**Michel DuCharme**

Defence R&D Canada

**Marie-Eve St-Louis**

Universite Laval

**Jean-Francois Gagnon**

Universite Laval

**Abstract:** We tested the effectiveness of a prototype simulation-based training procedure designed to support decision making in complex dynamic environments. An intelligent tutor was designed to monitor trainees use of over-simplifying heuristics throughout three scenarios and to discourage their use in a timely manner. Two test scenarios were used to assess training effectiveness: One involved a transparent problem structure while the other was partly opaque. Results showed a 34% decrease in the average use of the four heuristics monitored. However, goal attainment did not significantly improve in the test scenarios (heuristics were not replaced by better strategies). The training had a positive impact on participants ability to anticipate system behavior in the high transparency scenario but a negative impact in the low transparency scenario. We conclude that intelligent tutors should not only detract from using ineffective heuristics but also prescribe effective context relevant heuristics to overcome the wall of complexity.

# Evidence for a phonology-specific learning mechanism

**Regine Lai**

University of Delaware

**Jeffrey Heinz**

University of Delaware

**Abstract:** A series of comparative artificial language learning experiments were conducted to obtain evidence for or against the hypothesis that the mechanism responsible for learning phonological patterns in natural language is distinct from mechanisms responsible for pattern learning in other domains, including natural language syntax (Heinz and Idsardi, 2011, *Science*). Results from these experiments indicate that the hypothesis is correct.

Each experiment examined the learnability of one of three patterns in phonological, syntactic, non-speech auditory, and visual domains. These patterns are significant in different ways: pattern SH is attested in phonology; pattern FL is unattested in phonology; pattern NE is unattested in phonology, but attested in syntax. Results showed that SH was more readily learnable than FL in the phonological and the non-speech auditory conditions, but not the visual condition. Also, the performance of the phonological group was significantly different from the syntax group when exposed to the NE pattern.

# Deceptive strategy choice as decision making under risk

**Tei Laine**

Institute of High Performance Computing

**Kayo Sakamoto**

Institute of High Performance Computing

**Abstract:** Verbal deception often involves more subtle forms of deception than simply telling an outright lie. These different forms of deception are associated with different potential costs and benefits and thus constitute strategic choice options. To model this choice process, we treat deceptive strategy selection as decision making under risk; we assume that the speaker knows what gains can result from being deceptive (e.g., personal gain, preventing harm to others), and what she stands to lose if her deception is detected, or what losses would have resulted had she told the truth. We compare the computational model to data from human experiments in which we study whether people making deceptive strategy choices focus on inter-personal and situational factors, rather than on classical economic variables such as magnitudes and probabilities of potential losses and gains.

# Inner Speech and Task Switching in Adults

**Lucie Laurent**

MSHE, Besanon, Doubs, France

**Jean-Louis Millot**

Laboratoire de Neurosciences, Besanon, Doubs, France

**Patrice Andrieu**

Laboratoire de Neurosciences, Besanon, Doubs, France

Dpartement de psychologie, Universit de Fribourg, Switzerland

**Caroline Floccia**

School of Psychology, Plymouth University, United Kingdom

**fabien Mathy**

Universit de Franche-comt

**Abstract:** The aim of this study was to quantify the role of inner speech in categorical flexibility tasks. Research has shown that the suppression of inner speech in cognitive flexibility tasks leads to poorer performance by subjects. In contrast to previous studies, our objective was to offer tasks that enabled subjects to freely verbalize their reasoning, and to quantify its use. Using surface laryngeal electromyography to measure inner speech signals, we demonstrated that the more difficult the switching task, the greater the quantity of speech recruited by subjects when retaining and applying rules. Furthermore, our results show that relatively older adults ( $M = 50$  years) tend to rely on inner speech more than younger adults ( $M = 25$ ). We discuss the idea that speech acts as a support to executive functions and that it is needed to a greater extent with age due to declining executive performance.

# Enhanced Visual Processing in Perihand Space: Effects of Handedness

**Nathalie Le Bigot**

Leibniz Research Centre for Working Environment and Human Factors, Dortmund, Germany

**Marc Grosjean**

Leibniz Research Centre for Working Environment and Human Factors, Dortmund, Germany

**Abstract:** There is a growing body of evidence that visual processing is enhanced in perihand space. Some recent studies also showed that this enhancement is limited to the space around the right hand, at least in right handers. One explanation for these findings is that visual processing is facilitated at locations where action is more likely to occur. To test this notion, we had left and right handers perform a visual discrimination task under four hand-position configurations: Left only, right only, both hands, or no hands near the visual display. Results showed qualitatively different patterns for the two handedness groups. Visual sensitivity ( $d'$ ) was higher when only the left hand was near the display for left handers, whereas right handers performed better in the right- and both-hands conditions. These findings tend to confirm that visual enhancement is tied to the dominant hand, which is preferentially used for most manual actions.

# **The influence of cultural dispositions on the scene perception**

**Yoonkyoung Lee**

Pusan National University

**Bia Kim**

Pusan National University

**Yiwon Hyun**

Pusan National University

**Cheonwoo Shin**

Pusan National University

**Jaesik Lee**

Pusan National University

**HyunJung Shin**

Pusan National University

**Abstract:** We investigated whether people of individualistic disposition and those of collectivistic disposition perceive the natural scenes differently. It was hypothesized that the former pays more attention to the targets than the grounds, whereas the latter pays attention to the relation between the targets and the grounds as well as the targets themselves in the scene perception. In Experiment 1 where Korean individualists were contrasted with Korean collectivists, cultural disposition (individualism vs. collectivism), figure-ground relevance (naturalness vs. unnaturalness), and change of scene(no change vs. change of figures vs. change of grounds) were manipulated. The results of Experiment 1 showed that the collectivists respond to the unnatural scenes more sensitively than the individualists. The similar patterns were observed in Experiment 2 in which Korean as collectivists and European American as individualists were contrasted with each other. In sum, these results suggest that the collectivists who tend to see the scenes holistically respond to the unnatural scenes more sensitively than the individualists.

# **Framing Neuroethics: An Integrated-Unified Scientific Analogy (I-USA) Perspective**

**Sang Bok Lee**

Kangnam University

**Jonathan Jiseop Lee**

John F. Kennedy High School

**Abstract:** In mapping the hermeneutical scopes of neuroethics (Topics in Cognitive Science, 2(3), July 2010) the authors propose an Integrated-Unified Scientific Analogy (I-USA) model to delineate the complexities of moral dilemma we are facing critically. Based on meta-review (neuroethics in PubMed) and scientific analogy (Gentner, D., 2010) method, the authors conceptualize an I-USA model that optimally comprises multiple factors from the following disciplines: (1) neuroeconomics (2) neurogenetics (3) positive neuroscience (emotional activation, empathy and altruism, Tor Wagner, et al., 2002; Moritz de Greck, et al., 2011; Reuter, M., et al., 2010), (4) affective/cultural neuroscience (cultural values and differences, Wang, G., et al., 2011) (5) neurotheology (religious and spiritual, Ashbrook, J., 1989, 1992; Newberg, A. B., & Iverson, J., 2003; Lee, S. B., 1994, 1995), and (6) cognitive neuroscience (fMRI and neuroscientific, Tsukiura, T., & Cabeza, R., 2011; Cohen, M., 2001). The I-USA intends to optimally unify most of relevant factors for neuroethics.

# **How they pick out the answer in multiple choice questionnaire: Independent-self versus interdependent-self**

**Min-Seop Lee**

Seoul National University

**Jeong Ryu**

Seoul National University

**Dayk Jang**

Seoul National University

**Abstract:** Attentiveness to others is more likely to be a self-defining goal when the self is thought of as interdependent with others rather than independent of others. We predicted that interdependent self is more attentive in common ground than independent self in multiple choice questionnaire. In experiment 1, participants temporary self-construal was manipulated through a priming technique. As predicted, interdependence-primed participants were more likely than independence-primed participants to take the recipients knowledge into account and avoided providing redundant information in a self-administered questionnaire. Drawing on chronic differences in self-construal, experiment 2, replicated these findings with participants from independent and interdependent selves. The implications of these results for increasing understanding of behavioral priming effects in rich social contexts are discussed. Throughout, participants differential attentiveness to the common ground resulted in differential question order effects, raising important methodological issues for cross-cultural research; We expect to find culture differentiation between Korean to western people (USA or European etc.) as further study

# Information Structure, Alternatives, and Scalar Implicatures

Chungmin Lee

Seoul National University, Seoul, Republic of Korea

**Abstract:** Discourse occurs for information exchange in sentential utterances with information structure (IS). IS needs notions of Topic and Focus, Contrastive Topic (CT) and Contrastive Focus (CF). CT and CF are characterized in question answer conversation. A CT utterance comes from a QUD (Roberts 1996) with a Potential Topic (PT) consisting of a set of relevant alternative members, as a partial answer. Naturally, the question is not completely resolved and invokes a conventional scalar implicature. It is marked by a special intonation or morphemic marker and its implicature is not cancellable, hence conventional. The implicature generated is scalar with respect to the totality or qualitatively, in its DP or predicate PT.

CF is argued to invoke a closed set of disjunctive alternative possibilities. An alternative question is licensed if a pair or more of immediately relevant alternatives are available in the discourse context, as in Will you drink a tea or a coffee? It is semantically strengthened by the restriction exactly one disjunct holds (Pruitt & Roelofsens 2011) as in Inquisitive Semantics (InqSem). A correction answer is a typical CF: (1) Sue married Sam? Covertly, (2) Did SUECF marry Sam or did RITACF marry Sam? (From the immediately relevant alternatives set: Sue married Sam, Rita married Sam) (3) No, RITACF married Sam. All CF instances including pseudo-clefts, exhaustive focus, and CF-reduplication have (covert) AltQ. CF and AltQ in disjunction are likewise correlated. A conjunctively conceived CT is distinct from CF, conveying a scalar implicature, due to the unresolved partial information. CF and CT information structure is cognitively real. It is to be explored in terms of proposed possibilities in dynamic exchange.

# Observational category learning increases sensitivity to prototypical and correlational information

**Kimery Levering**  
SUNY Binghamton

**Kenneth Kurtz**  
SUNY Binghamton

**Abstract:** The traditional laboratory task of supervised classification learning tends to produce sensitivity only to information that discriminates between competing categories. Recent research broadening the study of category learning (e.g., inference learning) suggests that learners can be sensitive to structure beyond what is diagnostic. In previous work we interpreted these findings to reflect a generative (as opposed to discriminative) mode of learning and extended the phenomena to supervised observational learning of categories varying along two continuous dimensions. We now aim to demonstrate generative observational learning using binary dimensions. Categories were based on a uni-dimensional rule with within-category regularities in the form of a family resemblance structure (Experiment 1) or a perfect correlation between features (Experiment 2). Compared to classification learners, observation learners showed greater knowledge of both types of non-diagnostic structure. These results hold implications for how categories are learned and present a challenge to models grounded in discriminative category learning.

# The thinking behind decisions to spread disaster-related tweets

**Huaye Li**

Stevens Institute of Technology

**Rongjuan Chen**

Stevens Institute of Technology

**Yasuaki Sakamoto**

Stevens Institute of Technology

**Abstract:** Social media such as Twitter is playing a more and more important role in sharing information and coordinating disaster responses. However, after the 2011 Tohoku earthquake in Japan, Twitter users transmitted rumors about radiation and supplies, which Social media such as Twitter can play an important role in sharing information and coordinating disaster response. However, after the 2011 Tohoku earthquake in Japan, Twitter users transmitted rumors about radiation and supplies, which caused unnecessary panic. In the current work, we examined the thinking behind the decision to spread disaster-related tweets in Twitter. We showed subjects tweets related to the 2011 Tohoku earthquake. For each tweet, we asked them whether or not they would retweet it and the reason for their retweeting decision. Whereas thought of others (e.g., informative to others) played a major role when they decided to retweet, consideration of self (e.g., not interesting to me) dominated when they decided not to retweet. We further examined how factors such as source, familiarity, and importance of disaster-related tweets affect the retweeting decisions. Our results suggest techniques for minimizing the spread of false information during responses to disasters.

# Size Effect During Emergence of Symbolic Communication System Revealed by Agent-based Modelling

**Guanhong Li**

Japan Advanced Institute of Science and Technology

**Takashi Hashimoto**

Japan Advanced Institute of Science and Technology

**Abstract:** In the experiment proposed by Konno et al. (in press) about constructing a symbolic communication system, it had been confirmed that the emergence process includes three stages corresponding to three test conditions: no messaging, synchronous messaging and asynchronous messaging, respectively.

To investigate the mechanism of the emergence of symbolic communication system, an agent-based model is built using reinforcement learning.

The simulation result shows that: 1) for synchronous messaging condition, the number of rounds taken to get enough points to win tends to grow when increasing the size of selectable symbols; 2) for asynchronous messaging condition, the number of rounds before success remains stable even though more selectable symbols are offered.

We thus conclude that the size of selectable symbols has a negative effect on the formation of symbolic communication system under the synchronous messaging condition, while has no effect under the asynchronous messaging condition.

# Understanding human error detection as task interruptions

Simon Y. W. Li

Lingnan University, Hong Kong

**Abstract:** Experimental studies of human error detection have not made much progress since the 80s and 90s (e.g. Allwood, 1984; Rizzo et al., 1987; Sellen, 1994; Zapf et al., 1994). One of the reasons is because there is not an established methodological paradigm. A connection between interruption and error detection is proposed when an error is detected and corrected, it is similar to handling an interruption because the original task has to be suspended and resumed later. The connection is based on Trafton et al.s (2003) characterisation of interruption, which dissects interrupted activities into various measurable time-based components. A similar anatomy of the error detection process is proposed giving time-based measures such as detection lag, correction lag and resumption lag; error detection examples are discussed. The main contribution of the proposed characterisation is a methodological one postulating a set of dependent measures for future systematic investigations of the error detection process.

# **Assessment of childrens summarization ability: An alternative measure of reading comprehension**

**Chi-Shun Lien**

National Chung Cheng University, Chia-Yi, Taiwan

**Hung-Hui Chen**

National Chung Cheng University, Chia-Yi, Taiwan

**Abstract:** The ability to summarize information is important for understanding and remembering texts. Lacks of this ability, readers are not able to engage in the process of deleting, generalizing, and integrating those propositions of a text (Kintsch & van Dijk, 1978) and fail to comprehend the text. The purposes of this study were to evaluate a new diagnostic tool of text comprehension and scrutinize the development of childrens summarization ability. Sixty 3rd and 6th graders were recruited from an elementary school in Chia-Yi, Taiwan. All participants were administered 3 different versions of expository passages, which were deletion, generalization, and construction and asked to summarize them, respectively. A free-recall measure and a comprehension test were given after each summarization task. The findings indicated that the performance of summarization task was highly correlated to the performance of recall measure and comprehension test. In addition, there was developmental difference on the summarization task.

# Cross-linguistic Similarities and Differences in Causative Constructions

**Eunsuk Lim**

Hankuk University of Foreign Studies

**Kisuh Ahn**

Hankuk University of Foreign Studies

**Hee-Rahk Chae**

Hankuk University of Foreign Studies

**Abstract:** Language is learned on the basis of input and general cognitive mechanisms. We present a study on causative constructions in English, Korean and Portuguese. Causative constructions vary cross-linguistically, but we show that there is a possibility of some cross-linguistic generalizations among causative constructions in the three languages. We also point out some of the idiosyncratic constructions in each language, for example, the caused-motion construction in English. First, we divide causative constructions into three types: causation by command, causation by direct physical action and causation of emotion. Second, we group them into lexical, morphological and syntactic causation structures in terms of form-meaning pairings. Lastly, we examine the similarities and differences of the three languages focusing on their cognitive and psychological properties using a prototype model. We believe that this study will contribute to the understanding of the problems of common misuses of the causative constructions by children learning native languages as well as by adults learning foreign languages.

# Unpredictable Grunting in Tennis is More Distracting

**Ahnate Lim**

University of Hawaii at Manoa

**Alan Kingstone**

University of British Columbia

**Scott Sinnett**

University of Hawaii at Manoa

**Abstract:** Anecdotal and empirical evidence suggests that grunting in tennis can hinder an opponents performance. Here we addressed the question of whether a grunt is solely a distraction, or if instead it masks important auditory information carried by the dynamic multisensory event of the ball striking the racquet. Videos of a professional tennis player were played in silence, or included a grunt either before, during, or after impact, with the task being to judge the direction of the shot as quickly and accurately as possible. No differences were observed between the sound conditions, indicating that the adverse effects of grunting may be related to general distraction. This was replicated when manipulating the frequency of the grunts to occur 75% of the time, with overall performance improving, suggesting that the predictability of grunts is important, with more sporadic grunting leading to diminished performance.

# **Enhancing critical thinking and learning outcomes at the university: A pedagogical perspective**

**Stephen Wee Hun Lim**  
National University of Singapore

**Abstract:** Standard pedagogical strategies and assessment methods used for university undergraduate teaching normally involve knowledge transmission in classroom settings, student discussions, mid-term tests, student presentations on designated research papers and topics, and knowledge-based final exams that would not particularly help educators reach the goal of enhancing critical thinking and learning outcomes among students. This study explores dimensions beneath critical thinking and factors that would have contributed towards this goal, based on student evaluations gathered from a range of undergraduate modules taught by the author. Implications on general pedagogy and future directions will be discussed.

# Is it Possible to Train the Approximate Number System?

**Marcus Lindskog**

Uppsala University, Uppsala, Sweden

**Anders Winman**

Uppsala University, Uppsala, Sweden

**Peter Juslin**

Uppsala University, Uppsala, Sweden

**Abstract:** Humans are believed to be equipped with an Approximate Number System (ANS) that supports non-symbolic representations of numerical magnitudes. Acuity in the ANS is thought to progress developmentally from childhood to adolescence and to be related to mathematical achievement. However, from previous research, it is not clear whether it is possible to train this core ability. The present study investigates the effect of substantive corrective feedback on non-symbolic number comparisons, in an adult population, using a control group comparison design. The results indicate that even extensive training with feedback (1000 trials) has no effect on ANS-acuity. However, feedback induces a motivational effect on participants. These results suggest that some of the observed relationship between ANS-acuity and general math achievement may be mediated by a motivational factor and that a characteristic of the number sense may be its non-plasticity, at least for adults.

# **Cognitive Choreography in Mental Algebra Task**

**John Lindstedt**

Rensselaer Polytechnic Institute, Troy, New York, United States

**Wayne Gray**

Rensselaer Polytechnic Institute, Troy, New York, United States

**Abstract:** To understand the complexity of human cognition, it is important to account for how the various cognitive functions play off of one another during a complex cognitive task. This "cognitive choreography" was investigated previously in an attempt to tie cognitive functions to regional brain activity. The task used was a complex mental algebra task involving the combined use of various cognitive functions: problem representation, mental manipulation, memory retrieval, maintenance, and goal changing, as well as multiple modalities for input (auditory and visual) and output (manual and verbal). We present a faithful replication of this study's behavioral results (accuracy and latency), and discuss implications for cognitive functions in complex tasks.

# **Undergraduates' online search strategies and visual attention distribution**

**Wan-Yi Liu**

Graduate Institute of Digital Learning and Education, National Taiwan University of Science and Technology

**Meng-Jung Tsai**

Graduate Institute of Digital Learning and Education, National Taiwan University of Science and Technology

**Abstract:** The purpose of this study was to explore the relationship between the undergraduates online searching strategies and visual attention distribution by using eye-tracking technique. Thirty-one undergraduate subjects participated in the experiment in which they were asked to solve a task individually regarding the requirements for causing landslides. Participants visual attention distribution were measured with an eye-tracker. Students online searching strategies were assessed via a online information searching strategy inventory immediately after the online searching task. Results of this study revealed that students with higher prior knowledge can better identify relevant information from websites. And students with better problem-solving performance were found to spend more time reading relevant online information. In addition, students with better evaluation strategy were found to integrate the relevant information more efficiently. Furthermore, a significant gender difference was found in their visual attention allocated on the task problem and on the first page of search results.

# Action and affordances in nominal classifier systems

Marit Lobben

University of Oslo

**Abstract:** Although interdisciplinary research is increasingly being conducted on language and action within cognitive neuroscience, no one has looked into how the typological study of grammatical categories can be explained in terms of sensorimotor interactional learning. In this presentation cognitive semantic bases of nominal classifier systems are analysed in the light of the latest neuroscientific research within embodied cognition. Classifiers are found in unrelated languages in disparate areas of the world and are based on a restricted set of recurring semantic domains, e.g. an objects size, material, consistency, shape, dimension, inherent orientation, or function values. They therefore represent a justified area of study for general human cognition. It is demonstrated that embodied knowledge is necessary in order to use these grammatical components correctly in communication, relying on situatedness and perception in the conceptualisation process. Hypotheses of neural activation sites are proposed that accord with their modes of acquisition.

# **An ERP study on L2 grammatical aspect processing in Japanese**

**Shengyan Long**

Hiroshima University

**Yusaku Tsuyuguchi**

Hiroshima University

**Manami Sato**

Hiroshima University

**Hiromu Sakai**

Hiroshima University

**Abstract:** Second language learners process aspectual mismatch between verbs and adverbs differently from native speakers (Long et al., in press). Then, what about mismatch between grammatical aspect and adverbs? We explore into this question using event-related potentials (ERP), and compare our results with aspectual mismatch study with L1 Chinese speakers reported by Zhang & Zhang (2008).

Eleven Chinese speakers with high Japanese proficiency read Japanese sentences where aspectual property of adverbs either matched or mismatched with the progressive aspectual marker. Brain responses to mismatch were recorded by ERP.

Our results showed that violations of grammatical aspect elicited a 300-500ms posterior and left central negativity, which reflect resolving incompatibility of aspectual markers. This negativity is similar in its timing and distribution to the negativity reported in Zhang & Zhang (2008) for native speakers. This suggests that Chinese learners of Japanese process grammatical aspect as they do in their native language.

# **The Role of Embodiment on Childrens Memory Recall through LEGO Robotics Activities**

**Carol M. Lu**

Teachers College, Columbia University

**John B. Black**

Teachers College, Columbia University

**Seokmin Kang**

Teachers College, Columbia University

**Abstract:** Previous research has shown that embodied cognition involving body positions and physical enactment can enhance memory recall (Dijkstra et al., 2007; Scott et al., 2001). This study investigates the role of embodiment on childrens memory recall. Participants were fifth graders from two urban public schools attending a Robotics after-school program. They were asked to recall different LEGO Mindstorms sensors they used when constructing their robots and which of the physical science concepts were presented. Students were randomly assigned to one of the two learning conditions: science learning with robotics or science learning with robotics and embodiment. Students in embodied group outperformed the students in the robotics group. The results suggest that embodiment has remarkable potential to enhance childrens memory recall and performance on recognition tests, as compared to children without the embodied experience.

# **Social elements are not a must for preverbal infants learning in an interactive event**

**Yuen Ki Ma**

Department of Psychology, The University of Hong Kong

**Hiu Mei Chow**

Department of Psychology, The University of Hong Kong

**Jaclyn Yeung**

Department of Psychology, The University of Hong Kong

**Anna Wing Yee Ho**

Department of Psychology, The University of Hong Kong

**Chia-huei Tseng**

Department of Psychology, The University of Hong Kong

**Abstract:** Hamlin et al. (2007, 2010, 2011) showed that preverbal infants exhibit preference for animated figures in social events, and Chow, Tsui & Tseng (2011) demonstrated that infants can successfully associate visual (e.g. shape, color, and motion) cues with emotional cues (e.g. crying and laughing) which could be a prerequisite for making this social judgment. The current study examined whether infants ability of associated learning in complex sequences is limited to social-related situations only. After removing all socially relevant cues (eyes, facial expression, crying or laughing) from learning stimuli, we found 8 to 10-month-old infants could still associate agents with motion and neutral auditory outcomes. We also found the shape/color of a figure to be a more salient factor than the movement of the figure. We conclude that associated learning in animated interaction is not limited to specific social contexts in preverbal infants.

# **A possible source of phonological deficit in developmental dyslexia: Counter-evidence for universal phonological grammar**

**Norbert Maonchi-Pino**

**Jean Calle**

Laboratoire d'étude des Mécanismes Cognitifs, Université Lumière Lyon 2

**Ryuta Kawashima**

Dept. of Functional Brain Imaging, IDAC, Tohoku University

**Abstract:** Whether the phonological deficit in dyslexia ensues from impaired universal phonological grammar remains unanswered. Ten French dyslexic children were compared to chronological age-matched and reading level-matched controls. All were aurally-administered two syllable-counting tasks with di- and trisyllabic pseudowords (/am.al/; Exp. 1) or mono- and disyllabic pseudowords (/mal/; Exp. 2). We manipulated universal phonological sonority-related markedness within unattested onset clusters, from the phonotactically-unmarked clusters (/bal/) to the phonotactically-marked ones (/bal/). Sonority-related markedness was naturally inverted within intervocalic clusters. Across experiments, as sonority-related markedness decreased, response accuracy increased. Response patterns were similar in dyslexic children who were as accurate as both control groups, but systematically slower. Remarkably, an illusory epenthetic // vowel phonologically repaired marked clusters. Neither statistical properties nor acoustic-phonetic cues and reading skills accounted for the misperception/repair. Our results discard impaired phonological grammar as a source of dyslexics' phonological deficit and are discussed toward a deviant vs. delayed developmental course.

# **Aberrant sense of agency in patients with schizophrenia: confusion of temporal causality during intentional action**

**Takaki Maeda**

Department of Neuropsychiatry, Keio University School of Medicine

**Motoichiro Kato**

Department of Neuropsychiatry, Keio University School of Medicine

**Keisuke Takahata**

Department of Neuropsychiatry, Keio University School of Medicine

**Tsukasa Okimura**

Department of Neuropsychiatry, Keio University School of Medicine

**Hajime Asama**

Tokyo University

**Masaru Mimura**

Department of Neuropsychiatry, Keio University School of Medicine

**Abstract:** Self-disturbances in schizophrenia have been explained and studied from the standpoint of an abnormal sense of agency (SoA). We devised an original agency attribution task that evaluated explicit experiences of temporal causal relation between an intentional action and an external event, without any confounding from sense of body ownership. We demonstrated that an excessive SoA was observed in patients with prominent positive symptoms including delusion and hallucination. Moreover, those patients had a greater tendency to feel SoA even when external events were programmed to precede their action (backward causation). Therefore, patients felt both forward and backward exaggerated causal efficacy during the intentional action (Maeda et al., Psychiatry Research 2012). On the other hand, patients with predominant negative symptoms showed diminished SoA. Confusion in the experience of temporal causal relations between the self and the external world may underlie self-disturbances in schizophrenia. Aberrant SoA could be a fundamental vulnerability marker for schizophrenia.

# **Student perspectives on critical and other thinking skills: Some cultural similarities and differences**

**Emmanuel Manalo**

Waseda University

**Takashi Kusumi**

Kyoto University

**Masuo Koyasu**

Kyoto University

**Yasushi Michita**

The University of the Ryukyus

**Yuko Tanaka**

Stevens Institute of Technology

**Abstract:** The purpose of this study was to explore the views of students from different cultural backgrounds about good thinking skills, including those they perceive as required in their courses of study. Focus group interviews were conducted with undergraduate students from Kyoto (n = 8) and Okinawa (n = 7) in Japan, and from Auckland (n = 8) in New Zealand. Analysis of the students responses revealed commonalities in views about what good thinkers possess: these included many qualities associated with critical thinking. However, when specifically asked about the meaning of critical thinking, many of the students from Okinawa were uncertain, and the students from Auckland also referred to attributes not commonly associated with critical thinking such as intuition and positive thinking. The results suggest a need for more explicit instruction in critical thinking skills development as well as for greater clarity about thinking skills expectations in tertiary level courses.

# **The role of exploratory decision-making in enhancing episodic memory**

**Doug Markant**

New York University

**Sarah Dubrow**

New York University

**Lila Davachi**

New York University

**Todd Gureckis**

New York University

**Abstract:** Studies of episodic memory are typically passive in that the learner can't control the sequence and timing of stimulus presentation. This approach obscures how people alter their learning by choosing to study some items over others, a decision-making process with many implications for memory. Voss (2011) showed that when people made decisions about what to study their memory was better than when yoked to the decisions of another person, and they derived a specific benefit from revisiting recent items. The source of this benefit is unclear, however, since previous studies have not separated the effect of executing study decisions from that of resulting personalized study opportunities. By varying the decision-makers degree of control over the study experience, we show that people still benefit from making study decisions even when unable to revisit items or choose what material to study next, highlighting the role of decision-related processes in improving episodic encoding.

# Visual processing deficits due to HIV: Evidence from temporal order judgments

**Liron Marotz**

Department of Psychology, University of Hawaii at Manoa

**Scott Sinnett**

Department of Psychology, University of Hawaii at Manoa

**Cecilia M. Shikuma**

John A. Burns School of Medicine, University of Hawaii at Manoa

**Abstract:** Numerous empirical reports have demonstrated cognitive deficits after contracting HIV. While the majority of these findings have incorporated traditional neuropsychological tests (e.g., California Verbal Learning Test, Trail-Making), very little work has investigated visual temporal processing, and how spatial attention is distributed, and potentially adversely affected, by HIV infection. In this preliminary study we used a temporal order judgment task that required participants to accurately judge the successiveness of laterally presented asynchronous events. Attention was spatially directed by a peripheral cue prior to each trial, in order to assess deficits in orientation to reflexive cues. The findings demonstrated that people with HIV required more time to accurately judge temporal order when compared with a sample without HIV. However, the cue captured attention equally regardless of HIV status. The broader conclusion is that HIV may lead to impairment in visual temporal processing, without adverse effects on the distribution of spatial attention.

# Collaboration for Building Sustainable Knowledge

**Hiroyuki Masukawa**

Shizuoka University

**Ikuo Endo**

Ito City Higashi Elementary School

**Abstract:** We are investigating how collaboration leads to deeper understanding. We targeted sixth-grade math-classes. In the lesson, the teacher asked "What's the number of games of a round-robin football tournament?" In the first half, the children solved problem in groups, and in the second half, they reported their solutions and then the teacher explained the correct answer. We analyzed the protocol-data of two groups. One group discussed how to solve problems while sharing and comparing multiple levels of abstraction: conceptual, calculative, diagram, or concrete. The other group discussed only the concrete abstraction. At the end, both groups' children checked "I understand" on the self-evaluation sheet. One month later the teacher gave the retrospective test to children. The results were that one group could describe how to solve problems and the other group's ideas in detail, while the other group could provide only the answer and explain the other group members name.

# Increases in Childrens Semantic Organization Predict Category-based Reasoning

**Bryan Matlen**

Carnegie Mellon University

**Karrie Godwin**

Carnegie Mellon University

**Anna Fisher**

Carnegie Mellon University

**Abstract:** Prior research indicates a protracted developmental course in inductive reasoning based on category information (Fisher, Matlen, & Godwin, 2011). A possible explanation for the development of adult-like induction is the gradual reorganization of semantic-knowledge. To explore this possibility, we presented preschoolers (N=43), kindergarteners (N=22), first-graders (N=10) and adults (N=20) with blocks representing semantically-similar (e.g., chick-hen), physically-similar (e.g., lamb-swan) and same-habitat (e.g., whale-octopus) animals: Participants placed animal pairs on a board representing a zoo according to the degree of semantic-similarity. The distance between animals was taken as a measure of how closely participants represented the semantic concepts. Preschoolers exhibited considerable variability and were worse at discriminating between semantically-similar and non-semantically-similar dyads compared to older children and adults. Preschoolers scores on the semantic-space task were also correlated with performance on an induction task ( $r=0.46$ ;  $p=0.002$ ). These results are consistent with the possibility that the organization of semantic-knowledge underlies advances in category-based reasoning.

# Efficiency of the Cognitive Bias in Grammar Acquisition

**Ryuichi Matoba**

Toyama National College of Technology

**Makoto Nakamura**

Nagoya University

**Shingo Hagiwara**

Toyama National College of Technology

**Satoshi Tojo**

Japan Advanced Institute of Science and Technology

**Abstract:** This study investigates efficacy of cognitive biases for grammar acquisition. We present a simulation of virtual block world where a pair of a parent and an infant agent resides. When a parent takes an action and utters corresponding sentence, an infant guesses the meaning of the utterance from the situational change caused by the action. The infant tries to acquire a compositional grammar through an amount of utterances, and the grammar would be polished through generations. Through this process, we focus on how the symmetry and mutual exclusivity biases help this grammar refinement. We expect that the symmetry bias works to combine a situational change and an utterance, and that the mutual exclusivity bias contributes to solve the ambiguity between a situational change and an action; when the infant finds an utterance is already combined with a different meaning, he/she ignores the new pair of utterance/meaning by the latter bias.

# **CyclingMusic & CyclingMelody: A System for Enriching Scenery Experience in Cycling by Real-Time Synaesthetic Sonification of Passing Landscape**

**Masaki Matsubara**

University of Tsukuba, Tsukuba, Ibaraki, Japan

**Satoshi Kuribayashi**

Keio Research Institute at SFC, Fujisawa, Kanagawa, Japan

**Haruka Nukariya**

Keio University, Fujisawa, Kanagawa, Japan

**Yasuaki Kakehi**

Keio University, Fujisawa, Kanagawa, Japan

**Abstract:** When riding on a bicycle, many people enjoy looking over the landscape passing by. This study discusses how to enrich scenery experience in cycling. Since the scenery experience is based on an embodied perception, it is known as one of the tacit knowledge, thus enriching it is difficult. In order to overcome this problem, we focused on the feature of auditory sense. Human audition can accommodate dynamic information better than vision, and data sonification presumably represents time-series data more efficiently than data visualization. We constructed two systems named CyclingMusic and CyclingMelody that translate the perceived movement of the scenery and other visual impressions, such as hue, lightness and colorfulness, into music. The continuously changing view is captured with a web-cam and translated into MIDI events that are replayed instantaneously. This allows for a reflection of the visual impression, adding a sound dimension to the visual experience and deepening the state of perception. A practical experiment in cycling shows sonification makes participants deepen the spatial experience.

# Does a humanoid robot in front of you activate your mirror neuron system?

**Goh Matsuda**

The University of Tokyo

**Kazuo Hiraki**

The University of Tokyo

**Hiroshi Ishiguro**

Osaka University

**Abstract:** In the present study, we attempted to evaluate the human-likeness of a humanoid robot named Robovie by using near infrared spectroscopy (NIRS). Since the activity of the human mirror neuron system (MNS) is believed to reflect the perceived human-likeness of observed agents, we compared MNS activity during observations of an action performed by a human and Robovie. Seven males and ten females participated. There were four observation conditions such as live-human, live-robot, video-human and video-robot. In addition the participants executed the same action by their selves to confirm the location of motor-related brain areas. MNS activity was the largest in the live-human condition in line with previous studies. Our interesting finding was, however, that MNS activity was larger in the live-robot condition than the video-human condition. This suggests that we perceive a humanoid robot in front of us as a more human-like being than a videotaped human.

# The effects of exposure sequence and duration on mere exposure effect

**Ken Matsuda**

Yamaguchi University

**Eriko Sugimori**

Yale University

**Takashi Kusumi**

Kyoto University

**Abstract:** This study investigated how exposure sequence and a delay influenced mere exposure effect. We used neutral random shapes and controlled exposure sequence (heterogeneous (spaced) and homogeneous (unspaced)), exposure frequency (3, 6, and 9 times), and intervals between learning and judgment (5 min and 1 week). Fifty five participants were exposed to each stimulus, and 5 min and 1 week later, were asked to rate preference, familiarity, novelty, nostalgia, using a 5-point scale as well as recognition of old and new items. The result shows that, in judgments about preference, familiarity, and nostalgia, scores for the stimuli in homogeneous exposure condition rose after 1 week, although scores in heterogeneous exposure condition didn't change with a delay. In homogeneous and high frequent presentation, nostalgia occurred by an interval of one week, and that nostalgia raised stimulus preference and familiarity.

# The Computational Process of And-type Conditionals in Japanese

Michinao MATSUI

Osaka Health Science University, 1-9-27, Temma, Kita-ku, Osaka-Shi, Osaka, Japan

**Abstract:** Japanese has four types of conditional sentences: Nara-type, Reba-type, Tara-type and the natural consequence expression using To (And-type). Among these four types, only And-type conditionals cannot express counterfactuals. Masuoka (1993) says that the Japanese conjunction To (And) is an index which calculates the relevance between elements. This paper explains this phenomenon based on Relevance Theory (Sperber et al. 1986). Cognitive relevance between the information A and B is defined by correlation coefficient (CR1) or by Loose Symmetry Model (CR2, Shinohara and Nakano, 2007).

(1)  $CR1 = P(AB)/P(A)kP(aB)/P(a)$  (2)  $CR2 = (P(AB) + P(Ab)P(ab)/P(b)) / (P(AB) + P(Ab) + P(AB)P(aB)/P(B) + P(Ab)P(ab)/P(b))$

In the expression of counterfactuals, the relation  $P(a) = P(ab) + P(a\bar{b}) = 0$  is trivial. Therefore, CR1 is computable only when the coefficient k which means the frame range of anti-factual situation equals zero. This computation leads the result of impossibility of And-type counterfactuals. On the other hand, CR2 cannot explain this impossibility because CR2 is always infinite. Therefore, CR1 is the better definition than CR2.

# Connecting input filtering and selection in language evolution

**Luke Maurits**

University of California, Berkeley

**Tom Griffiths**

University of California, Berkeley

**Abstract:** Previous work has demonstrated the formal equivalence of simple models of cultural evolution, based on iterated Bayesian learning with symmetric Dirichlet priors, with neutral models of biological evolution. This demonstration was profitable in allowing the use of existing mathematical results from population genetics to be applied to questions of language change. We extend this work by exploring parallels between more complicated models of cultural evolution, featuring input filtering, and models of biological evolution with selection. We investigate the use of analytic expressions for steady-state distributions for predicting the outcomes of cultural learning models, and apply these methods to the explanation of historical word order change via input filtering. In addition to these practical outcomes, our work relates to the broader question of just how similar linguistic and other cultural change is to Darwinian evolution in biology, and how valid it is to speak of cultural traits being selected for.

# When Lexical Development does not Spurt; the Case of Williams Syndrome Children

Julien Mayor

University of Geneva, Geneva, Switzerland

**Abstract:** Williams Syndrome (WS) children possess relatively large vocabularies when compared to their other, impaired, cognitive skills. However, their language acquisition is delayed, their vocabulary does not spurt, categorisation skills are weak and they do not respond taxonomically.

We mimic WS categorization impairments by hindering the formation of visual categories in a model of early word learning (Mayor & Plunkett, 2010). In the absence of lesions, the model accounts for the emergence of taxonomic responding and displays a vocabulary spurt driven by the formation of categorical representations. In contrast, when categorisation is impaired, lexical acquisition is delayed, a vocabulary spurt is absent and word-object associations are not generalised. However, through repetitive labelling events, the system is still able to acquire a large "proto-lexicon" by gradually attaching several exemplars of a category to their appropriate sound pattern in an associationist mechanism, thereby leading to the formation of a surprisingly large vocabulary.

# Self-directed information selection aids learning of logical rules

**John V. McDonnell**

New York University Dept. of Psychology

**Devin Domingo**

New York University Dept. of Psychology

**Todd M. Gureckis**

New York University Dept. of Psychology

**Abstract:** In self-directed learning tasks, participants can control the sequencing and timing of information presentation. In contrast, the existing literature on category learning has focused on passive learning paradigms, wherein information is presented to the learner randomly or in a pattern determined in advance by the experimenter. To explore the impact of self-directed learning on categorization performance, we compared passive and self-directed learning in the seminal Shepard, Hovland, and Jenkins (1961) category learning tasks. Participants learned by actively querying the category membership of individual exemplars in an array or by passively viewing labeled examples. We found that active learners exhibited significantly faster learning than passive learners. In addition, the benefits of self-directed learning were not uniform, but varied as a function of the category structure. Our results suggest that differences in interaction with learning materials can alter the difficulty of learning problems, independent of the abstract structure of the underlying rule.

# Making and breaking procedural conventions in dialogue

Gregory Mills

University of Edinburgh

**Abstract:** A key problem for models of dialogue is to explain how co-ordination is established and sustained. Existing accounts emphasize the importance of interaction, demonstrating how collaborative feedback leads to more systematized, stable, arbitrary and partner-specific referring conventions.

However, in addition to conventionalizing referring expressions, recent work demonstrates how interlocutors also rapidly establish procedural conventions for resolving sequential and temporal co-ordination problems in the interaction. It is unclear, however, whether interlocutors associate these procedural conventions with specific conversational partners.

To address this question, we report a collaborative, 3-participant, computer-mediated task which presents participants with the recurrent co-ordination problem of ordering their actions and utterances into a single sequence. Artificially generated clarification requests are inserted into the dialogue, that appear, to each participant, as if they originate from either of the 2 other participants. We argue that participants' responses to these clarifications provide evidence of interlocutors associating procedural conventions with specific partners.

# **Expanding childrens perspectives on art work by robot participation**

**Masaki Miyake**

Aichi Shukutoku University, Nagoya, Aichi, Japan

**Tomoki Hirano**

Museum Plus

**Naomi Miyake**

University of Tokyo

**Abstract:** In order to promote skills of art appreciation of novices, we have been investigating the effects of dialogue. Our practice encourages each participant to take her/his own viewpoint to find something meaningful to her/him in the artwork, express it verbally to be shared by others. The effect has been recognized widely experientially at schools and museums, yet the cognitive mechanisms of this facilitation have not been fully investigated. In this study we have used a remotely operated robot to provide a group of 10 to 15 kids of 8 to 10 year olds with a perspective not shared by them, to see whether such intervention could expand the groups scope of appreciation. The robot was accepted as a friend with its own ideas, and we identified cases of such facilitation. We will report the details of these successful cases, to explore the mechanisms of this method.

# **The effect of harmonization between word meaning and typography impression on implicit memory**

**Kozue Miyashiro**

University of Tsukuba, Tsukuba, Ibaraki, Japan

**Etsuko T. Harada**

University of Tsukuba, Tsukuba, Ibaraki, Japan

**Abstract:** This study examined the effect of harmonization between word meaning and typography impression on implicit memory. In a preliminary experiment, we asked undergraduate students the degree of harmonization (how much does the typography match its word meaning?) for 153 words, showing them two lists (hiragana and kanji) with three different typographies. Based on the results, an incidental memory experiment was executed with three experimental factors: the scripts at learning (hiragana, kanji, or no learning), with/without the harmonization at learning, and the typography at testing (same as learning, different neutral typography), as within participant factors. Both a word completion task and an old/new recognition test were executed using only hiragana. The result showed that harmonization facilitated implicit memory with hiragana-learned words, but implicit memory was reduced for kanji-learned words. Morphologically-based processing occurred when word meaning and typography were harmonized. Conceptual implication of this harmonization effect will be discussed.

# **Short-term memory for tonal and verbal information: Comparison with absolute and non-absolute pitch possessors**

**Shiho Miyazawa**

Tokyo Woman's Christian University

**Akihiro Tanaka**

Tokyo Woman's Christian University

**Takehiko Nishimoto**

Waseda University

**Abstract:** This study examined the difference in the storage of pitch and phonological information in absolute pitch (AP) and non-AP (NAP) possessors. In a recognition task using musical tones (pitch information), speech sounds (phonological information), and visual patterns, participants were asked to retain two stimulus sequences. In the same type condition, the nature of the first and second stimulus set was different (e.g., one sequence was musical tones and the other was speech sounds). In the different type condition, the nature of the two sequences was the same (e.g., both sequences were musical tones). We found that, in NAP possessors, the recognition rate of musical tones and speech sounds in the different type condition was higher than in the same type condition. In AP possessors, however, the recognition rate of musical tones revealed no difference between these two conditions. These results suggest the use of different strategy in retaining musical tones between AP and NAP possessors.

# **Behavioral priming contributes to the subsequent recognition performance**

**Kiyohumi Miyoshi**

Kyoto University

**Hiroshi Ashida**

Kyoto University

**Abstract:** The present study assessed the impact of behavioral priming in several tasks (semantic, color-decision and phonological tasks) on the creation of new explicit memory. In this study, Japanese words written in Kanji were repeated once in an incidental encoding task and explicit memory for the words was unexpectedly tested afterwards. The words associated with more behavioral priming in the semantic task were better recognized in the subsequent explicit memory test than were the words with less priming. Moreover, the subjects who demonstrated greater priming in the semantic task performed better in the explicit memory test. These results suggest that behavioral priming enhances the creation of explicit memory.

# **How much do you trust me? Economic decision-making and ingroup and outgroup membership**

**Rosalba Morese**

**Bruno G. Bara**

Center of Cognitive Science, Department of Psychology, University of Turin; Neuroscience Institute of Turin, University of Turin, Italy

**Abstract:** Cross-cultural studies suggest that culture can influence human decision making, especially in economic contexts, but little is known about economic decision-making comparing ingroup and outgroup membership. We studied trusting behavior in two different cultures: the Chinese one, example of collectivist culture, and the Italian one, example of individualistic culture (N=25 Italians and N=25 Chinese). Using a modified version of the Trust Game with three levels of trust (20 or 40 or 60 Monetary Units), we investigated behavioral differences in decision-making based on trust levels in ingroup (Player A and B same nationality), and outgroup condition (Player A and B different nationality). Data analysis showed that both groups tend to trust more when the amount of monetary units decreases. Furthermore, results revealed no statistically significant differences in the trusting behavior between ingroup and outgroup factor for both cultural groups.

# Using syntactic priming to facilitate the language production of novice Japanese EFL learners

Miwa Morishita

Kobe Gakuin University

**Abstract:** Syntactic priming is the tendency for language users to produce a particular syntactic structure soon after listening to or reading that structure. Previous research using Japanese EFL learners found that intermediate learners were affected significantly more by syntactic priming than novice learners in a sentence completion task mainly because the grammatical/syntactic information might not be fully represented in the mental lexicon of the latter (Morishita, 2011; Morishita, Sato, & Yokokawa, 2010). Morishita and Yokokawa (2011) found, however, that the more novice learners were exposed to certain sentence structures, the stronger the priming effects became, where repeated exposure might aid implicit learning through imitation and practice. This presentation will discuss the results of the above research, as well as those of an ongoing experiment based on a scripted interaction task, in order to assess the possibility of using syntactic priming to facilitate the language production of novice Japanese EFL learners.

# Speed reading training and visual span

Aiko Morita

Hiroshima University, Higashi-Hiroshima, Hiroshima, Japan

**Abstract:** The current study investigated the span training effect on size of visual span and on reading speed. The visual span for reading refers to the range of letters, formatted as in text, that can be recognized reliably without moving the eyes. It has been hypothesized that the size of the visual span imposes a fundamental limit on reading speed. However, the relation between visual span expansion and reading speed increase has not been clarified. The present study conducted two types of training: One was the word recognition training. Eight undergraduate students were trained to recognize three or four words simultaneously. The other was the saccade training. Ten students were trained to read texts with larger saccades. The results showed that participants reading speed increased by 30% in both training groups. The word recognition training was more effective than the saccade training on visual span expansion, especially on left visual field.

# **Analytical method of Japanese folk tale for story generation**

**Hitoshi Morita**

University of Nagasaki, Nagayo-cho, Nagasaki Pref., Japan

**Abstract:** The purpose of this research is to examine whether a new story can be created by analysing folk tales. The tools of folklore like the tale type and the motif indexes are used for the analysis. The original text of this research is "Momotaro" (Peach Boy). This story had taken a rejuvenation motif until Edo period (19C). I examine 4 factors converted from the rejuvenation to the abnormal birth motif: 1)Prosperity of popular literature, 2)Enactment of elementary school textbook, 3)Diversion of folklore to nationalism, 4)Fight uplift animation in World War II. Next, I show the structure of the story from the following points. Process of the birth, Hero's name, Attendants, Motivation of departure, Strategy of demon extermination, Return to home. I clarified how this story was influenced from the society. Then, I examine to generate the text by analyzing "Momotaro", and compared with the Japanese 5 great folk tales.

# Facilitation and inhibition in the spatiotemporal template for detecting target ring

**Masayoshi Nagai**

National Institute of Advanced Industrial Science and Technology (AIST)

**Patrick J. Bennett**

McMaster University

**Allison B. Sekuler**

McMaster University

**Abstract:** Using the classification image technique (Ahumada, 1996), this study investigated the nature of spatiotemporal facilitatory and inhibitory templates when detecting a target ring. The stimulus consisted of fifteen temporal frames of five spatial elements: one-center disk and four-surrounding concentric rings. When a target was present, the middle brighter ring than the screen background always served as the target, and the rest of the elements were darker than the background. Random luminance noises were changed on every stimulus frame. On a non-target trial the non-target pattern was presented across all 15 frames. On a target trial the target pattern was presented at the middle three temporal frames. Results showed a transient facilitatory response at the target location around the target presentation and an inhibitory response from the outer elements even after the targets actual presentation. These results suggest that spatiotemporal templates are not simple copies of the spatiotemporal target pattern.

# **Analysis method focusing on repeated and not repeated verbalizations during human interface operation**

**Yukari Nagai**

School of Knowledge Science, Japan Advanced Institute of Science and Technology, Japan

**Saori Noda**

HMI R & D Department, DENSO CORPORATION

**Georgi V. Georgiev**

Department of Mechanical Engineering, Kobe University, Japan

**Toshiharu Taura**

Department of Mechanical Engineering, Kobe University, Japan

**Deny Willy**

School of Knowledge Science, Japan Advanced Institute of Science and Technology, Japan

**Abstract:** Humans interact with and operate different devices and ultimately form impressions, such as like and dislike. In previous research, humans impressions of devices with regard to various operations, were not considered. Human impressions are difficult to capture, as they tend to be ambivalent. This study investigates an analysis method that focuses on repeated and not repeated verbalizations during human interface operation. The study included an experiment in which six subjects were asked to freely verbalize their impressions of device operation of two devices in two vehicles. The words from the verbal protocols are analyzed using concept networks that are formed of associative word pairs. This analysis outlines a complex associative layer of impressions that the verbalizations are drawn from. The result suggests that the impressions from both verbalization types repeated and not repeated identify undefined issues in the operation of interfaces. Thus, methods for resolving these issues can be formulated.

# **The effects of listeners familiarity with a talkers voice on the speech recognition in noisy condition**

**Chikako Nagaoka**

Graduate School of Human and Environmental Studies, Kyoto university, Kyoto, Japan

**Naoshi Hiraoka**

Academic Center for Computing and Media Studies, Kyoto university, Kyoto, Japan

**Shintaro Funahashi**

Kokoro research center, Kyoto university, Kyoto, Japan

**Abstract:** The present study examined whether listener's familiarity with a talker's voice improved speech recognition in noisy condition. Subjects were asked to perform word and sentence intelligibility task in noisy condition under following three conditions; (1)subjects heard familiar voice and were informed who was speaking (explicit-familiar condition), (2)subjects could hear familiar voice but were not informed who was speaking (implicit-familiar condition), (3)subjects heard unfamiliar voice and were not informed who was speaking (novel condition). We used subject's friend's voice as a familiar voice. As a result, the percentage of correct answer of explicit-familiar condition and implicit-familiar condition were better than that of novel condition, but there was no significant difference between explicit-familiar condition and implicit-familiar condition. Present results revealed that the familiarity with a talker's voice improved speech recognition in noisy condition, while knowing who was speaking did not influence speech recognition.

# **A Comparison of Experienced, Novice Counselor and Non-counselor in Recall of Client-Presented Information in Therapeutic Interview**

**Chika Nagaoka**

Kyoto University

**Sakiko Yoshikawa**

Kyoto University

**Tomoko Kuwabara**

Kyoto University

**Yasuhiro Oyama**

Kyoto University

**Chiriho Hatanaka**

Ritsumeikan University

**Motoki Watabe**

Waseda Institute for Advanced Study

**Masashi Komori**

Osaka Electro-Communication University

**Abstract:** This study examines whether counselors memory of client-presented information varies qualitatively according to the number of years of counseling experience. This study develops a methodology to measure the amount of counselors recall memory obtained from a free recall task after watching videotaped stimulus interviews. Four experienced counselors, seven novice counselors, and twelve non-counselors watched videotaped stimulus interviews and then wrote freely everything they could recall about what the client had said in the interview. Interview transcripts were employed as evaluation criteria. Independent coders judged the parts of the transcript to which the recalled items corresponded. The results indicate that the experienced counselor group scored the highest in recalling client-presented information and that recalled contents differed among the participant groups. Implications of the steps to gain counselor expertise are discussed.

This study was supported by Grant-in-Aid for Scientific Research (No. 20530569) from the Japan Society for the Promotion of Science.

# The Narrative Structure of Nostalgia Cognition and Film

**Yuya Naito**

HOSEI University Graduate School

**Akihito Kanai**

HOSEI University

**Abstract:** This study inspects re-defining nostalgia and re-modeling the narrative structure of nostalgia cognition. To re-define nostalgia, we use mainly three kinds of nostalgia by Davis (1979), which consists of simple nostalgia reflexive nostalgia and interpreted nostalgia. The narrative structure of re-defined nostalgia cognition is consisted with the three kinds of nostalgia. The re-defined nostalgia includes not only affirmative but also negative factor. This study includes analyzing of films and experiments, which are investigating whether the three kinds of nostalgia is cognized by using the programmed materials. The materials are able to change the past and current scenes of films controlled by the computer programming. These analysis of films and experimental results suggest that some films can enable a viewer experience various kinds of nostalgia. On the other hand, other films can enable a viewer experience only a factor of nostalgia or not at all.

# TCieX: An Approach toward Communicating Weight through Pseudo-Haptic Feedback Mechanisms

**Kumiyo Nakakoji**

Software Research Associates, Inc., Japan

**Yasuhiro Yamamoto**

Tokyo Institute of Technology

**Abstract:** The notion of weight is useful to represent not only the mass of an object, but also the physical feedback for a remote interaction as well as the importance of a concept. Existing human-computer interaction design has communicated weight primarily through the three means: symbolic representation ("240g"), kinesthetic interaction (by wearing a physical actuator), and haptic feedback (by applying low-frequency stimuli to the forearm). Our approach uses a fourth means that uses the visual and audio interaction to communicate weight, stiffness, or viscosity through pseudo-haptic feedback mechanisms. Pseudo-haptic feedback stimulates haptic sensations without using a haptic interface but using dynamically changing visual and audio representations in terms of the hand movement.

We have built TCieX (Touch-Centric interaction embodiment eXploratorium) as a collection of interaction test suites, with which a user produces a variety of combinations of temporal, visual, and auditory representations for different types of simple object movement through different C/D (Control/Display) ratios and mapping profiles. By using TCieX, an interaction designer explores a design space of visual and auditory representations to produce a desired effect of pseudo-haptic sensations.

# **The effects of paralinguistic cues in a teachers responses to the students utterances in a moral class**

**Keiko Nakamoto**

Bunkyo University

**Ayumi Nishiyama**

Bunkyo University

**Abstract:** This study investigated the characteristics of a teachers paralinguistic cues in a moral class in a Japanese elementary school. In the class, the children were told a story on friendship and were asked to give their views on it. In the study, the teachers responses (in particular, thats right, I see, and great) to the childrens utterances were analyzed in terms of paralinguistic characteristics. The results show that the response thats right was used fewer times in the learning activities during which the teacher asked the children to think deeply than the other activities. Moreover, during such activities, the teachers responses were made with a monotonous intonation and in a relatively low voice. Correspondingly, the children paused more often when giving their views during this activity as compared to the other activities. These results suggest that paralinguistic cues are attached consciously or unconsciously to the teachers responses, and they affect the behavior of the children during learning activities.

# **An agent-based model for the emergence of creoles**

**Makoto Nakamura**

Nagoya University

**Shingo Hagiwara**

Toyama National College of Technology

**Satoshi Tojo**

Japan Advanced Institute of Science and Technology

**Abstract:** This study investigates the emergence of creoles through computer simulations of language contact in an artificial community. Creoles are full-fledged new languages which infants growing in a multilingual community acquire as their native language. We define a creole in the agent community as a new language dominating the community. We have developed an agent-based model with Kirby (2002)'s Iterative Learning Model where agents are connected with neighbors on a social network. The infant agents acquire a compositional grammar, hearing utterances from their parents and neighbors. Assuming language exposure plays a key role for creolization, we introduce a parameter of exposure to neighbors to the model. Language groups result from clustering similar languages, each of which is spoken by an agent. Experimental results show a certain degree of the exposure is necessary for creolization. Further investigation suggests that the structure of the social network affects that of agents' grammars.

# Generating new product ideas by assemblage of different product components

**Jun Nakamura**

Kanazawa Institute of Technology

**Yukio Ohsawa**

University of Tokyo

**Abstract:** This research is focused on clarifying the effect of providing information, where synthesis of different product components provides with an implication for generating new product ideas.

We hypothesize that generating new product ideas is induced by unexpected assemblage of presented different product components. This hypothesis was evaluated by analyzing playing logs of a developed Web based tool to enjoy assemblage of elements whereof categories are consisting of three components, i.e., purpose, function and material.

We defined generating new product ideas is associated with possible architectural compatibility. As a result of 11 players, we found that generating ideas tends to be either visible products or invisible products as a service, depending on ones attention to purpose at initial stage, e.g., the more purpose is considered, the more ideas are relatively visible products. In addition, the meaning of purpose has been interpreted as means to new product ideas.

## **Postal Addresses as an Assay of Cultural Cognition**

**Hiroko Nakamura**

Nagoya University

**Hiroshi Yama**

Osaka City University

**Gary L. Brase**

Kansas State University

**Nasriah Zakaria**

University of Science, Malaysia

**Yoshiko Arai**

Osaka City University

**Norhayati Zakaria**

The University of Wollongong, Dubai

**Shafiz A. Mohd Yusof**

The University of Wollongong, Dubai

**Jun Kawaguchi**

Nagoya University

**Abstract:** Present study investigated the cultural difference in explicit and implicit semantic processing in three countries: Japan, Malaysia and United States. In the experiments, we conducted both explicit and implicit priming tasks with state and city names as stimuli. Participants were required to judge whether the target city or state name was a real one or a fake one. The results indicated direction between prime and target (state-to-city or city-to-state) had no effects on amount of priming. The cultural difference was significant only in the explicit priming task: amount of priming was larger in Malaysian participants compared to both American and Japanese participants in SOA700, while there were no cultural differences in SOA200. These results imply Malaysians are engaged in more context dependent cognition; in other words, participants consciously use a prime as a context cue to anticipate a target item. And this cultural difference was disappeared in implicit semantic processing.

# **Changes in social motivation, and learning strategies, in PBL.**

**Yoshifumi Nakanishi**

Faculty of Education, Mie University, Tsu, Japan

**Takatoyo Umemoto**

Graduate School of Education and Human Development, Nagoya University, Nagoya, Japan

**Kenshiro Tanaka**

Graduate School of Education and Human Development, Nagoya University, Nagoya, Japan

**Abstract:** Problem/Project-Based Learning (PBL) is a method of learning in which students solve problems or complete projects. To solve problems or complete projects, students work collaboratively in small groups. Through PBL, student motivation is expected to be enhanced, so this study investigated students motivational changes in PBL. Thirty-four undergraduate students who attended the PBL class were asked to complete questionnaires on 3 occasions; at the beginning, in the middle and at the end of the class. Questionnaires contained scales relating social motivation, and learning strategies. The results show that one dimension of social motivation (motive to be evaluated) increased in the process of PBL. The relationship of social motivation and learning strategies are discussed.

# **Phoneme exchange in, serial-position effect on, and lexical/semantic contributions to single-word production: An investigation using speech-error induction techniques in Japanese.**

**Satoru Saito**

Kyoto University, Kyoto, Kyoto, Japan

**Abstract:** Serial-order control is a fundamental aspect of speech processing, and analyses of speech errors provide clues to the mechanisms that control this phenomenon. The present study employed a speech-error induction technique to identify speech errors that strongly resembled recall errors observed in verbal immediate serial recall. In three experiments, participants repeatedly produced a target word/nonword and, immediately before the utterance, were unexpectedly exposed to an auditory distractor word/nonword, which was either phonologically similar or dissimilar to the target. This technique successfully induced within-word phoneme exchange/transposition errors and elicited a within-word serial-position effect. On the other hand, lexical/semantic variables (e.g., lexicality of the target) led to only a very weak effect. We discussed mechanisms for the retention and production of a phoneme sequence in the context of these results.

# **An Analysis of Disfluencies in the Actor's Speech for Character Design**

**Seung Suk Nam**

Sogang University

**Hye Rhang Cho**

Sogang University

**Sook Whan Cho**

Sogang University

**Abstract:** This paper presents an analysis of quantified characteristics of Disfluency pattern of a leading South Korean film actor Kang-ho Songs Speech for character design in No.3 (Comedy, 1997), Memories of Murder (Thriller, 2003) and Thirst (Melodrama, 2009). Disfluencies, such as filled pause, repeated words, and repair or repetition utterance, are prevalent in spontaneous spoken language and show remarkably regular trends in a number of dimensions (Elizabeth Shriberg, 1994). The transcriptions of the actor's speech with disfluencies and variables in above films are analyzed, which might affect fluency rates in a corpus. It will be seen that the rates of disfluencies, induced by artificial manipulations, reflect the psychological state of a character. The actor's disfluency rates were relatively increased in Comedy and Thriller than Melodrama. Disfluencies are related with these cinematic factors: movie genre, actor role. Reflecting these features, we then recognize the acoustic features needed for character design.

# **The effect of a childbirth psychoeducation program on postnatal depression**

**Fei Wan Ngai**

The University of Hong Kong

**Sally Wai Chi Chan**

National University of Singapore

**Abstract:** The purpose of this study was to evaluate the effect of an antenatal childbirth psychoeducation program, which focused on teaching cognitive restructuring skills and problem solving strategies, on postnatal depression. Cognitive-behavioral strategies focus on challenging and changing dysfunctional cognitions and maladaptive behaviors that are believed to play a role in minimizing the risk of depression. This study used a mixed method design. The findings showed that women receiving the program had significant improvement in depressive symptoms compared to the control group during pregnancy and at 6 weeks and 6 months postpartum. Women perceived the program to be helpful in fostering the development of cognitive-behavioral skills, enhancing their confidence in taking up the maternal role, and improving their emotional control in the perinatal period. The findings provide empirical support for the feasibility of the childbirth psychoeducation program for promoting perinatal health and minimizing the risk of postnatal depression.

# **Satisfaction evaluation and time perception for waiting time in ICT usage under dual task situation**

**Sumaru Niida**

KDDI R&D Laboratories Inc. and University of Tsukuba

**Satoshi Nakamura**

University of Tsukuba

**Tomomi Moroga**

University of Tsukuba

**Etsuko T. Harada**

University of Tsukuba

**Satoshi Uemura**

KDDI R&D Laboratories Inc.

**Abstract:** Waiting is a potential source of frustration in human-computer interaction over network. The purpose of our research is to clarify a cognitive process of waiting for solving the problem, and we investigated satisfaction evaluation and time perception for waiting in human-ICT interaction under dual task situation. Participants were assigned to one of two primary tasks, evaluation of satisfaction or time length while waiting until the e-mail has been sent. Simultaneously, they executed one of two secondary tasks, calculating a consecutive numbers or solving a crossword puzzle. Result showed that the crossword task has stronger influences than calculation task in general, and surprisingly showed decrease of satisfaction with short waiting time, while showing shortening of psychological time with longer waiting time. That is, events associated with waiting process affect satisfaction evaluation and time perception in different ways. The frustration while waiting cannot be explained purely by length of psychological waiting time.

# Multimodal Interactions Development Process in Collaborative Creation

**Koshi Nishimoto**

Doshisha University

**Mamiko Sakata**

Doshisha University

**Abstract:** We have tried to quantify communication, both in terms of verbal and non-verbal processes, in collaborative activities using collaborators engaged in a creative task as our study subjects. This study involved a production task using LEGO blocks. The study subjects consisted of a total of ten groups; five groups made up of three men and another five, of three women. In an earlier study conducted by the same writer using male-only subjects, the group rated to have produced a work of greater perfection used a number of gestures to communicate, while the group rated to show a high level of originality was engaged in conversation unrelated to the task. The current study repeated a similar experiment using women subjects under the same conditions. We analyzed the modes of communication generated in collaborative activities and the differences between men and women, both in terms of verbal and non-verbal processes.

# Task complementarity and response complementarity in the social Simon effect

**Akio Nishimura**

Sophia University

**Koh Miyamoto**

The University of Tokyo

**Kazuhiko Yokosawa**

The University of Tokyo

**Abstract:** When two individuals sitting adjacently engage in separate but complementary go/no-go tasks, with each responding to only one of two non-spatial attribute (e.g., color; one to red and the other to green) of a stimulus presented on right or left sides, responses are faster when the actor and the stimulus are on the same side. The present study investigated the role of task complementarity in this social Simon effect by assigning same (e.g., red/green) or different (e.g., red/square) target feature dimensions (color/shape) to the two participants. We also investigated the role of response complementarity by manipulating the proportion of trials to which both, one, or neither of the participants responded. A comparable social Simon effect was obtained irrespective of target or response complementarity. We conclude that what is represented in the social Simon effect is the action, rather than the task, of the adjacent partner.

# **Reflexive orienting to others gaze is modulated by the accuracy of recognition of emotional facial expressions.**

**Yuka Nishiyama**

Nagoya University

**Jun Kawaguchi**

Nagoya University

**Abstract:** This study investigated the underlying mechanism of how emotional facial expressions modulate reflexive orienting to others gaze. We conducted gaze-cueing studies (e.g. Friesen & Kingstone, 1998), using dynamic emotional facial cues (i.e. happy, anger, fearful, and neutral expressions). A facial cue with gazing either left or right was presented. Participants were asked to indicate a position of the target that appear either at the looked-at (valid) location or the invalid location as quickly as possible. Subsequently, Participants were asked to classify each facial expression by a forced choice in the recognition task. It was revealed that fearful expressions facilitated the gaze-orienting effect compared to other expressions, only when the recognition of facial expressions was more accurate. The findings indicate that the accuracy of recognizing emotional facial expressions at the early perceptual stage influence the reflexive orienting to others gaze.

# **A Case Study of Meta-cognitive Exploration of Facial Expressions**

**Takeshige Nishiyama**

Keio University

**Hiromi Ochiai**

National Museum of Emerging Science and Innovation

**Yuko Toukairin**

Keio University

**Masaki Suwa**

Keio University

**Abstract:** We live among and belong to various social communities. Relationships and bonds with these communities are formed by daily communications. There are two main communication channels: verbal and non-verbal. Non-verbal communication channels are important for creating relationships within communities. Facial expressions are formed implicitly, and it is difficult for a person to know his/her expressions when having a conversation. Thus, we present a case study in which participants explore their own facial expressions by taking photos while having conversations. The process of the exploration includes taking photos, categorizing and labeling each expression, and making a pictorial book using these photos. Through this process, participants were able to know his/her expressions explicitly, which allowed them to reflect on their interactions within conversations. This indicates that, the process encourages meta-cognitive explorations by participants. Therefore, the participants gain new insight on their daily communications.

# **A cognitive emotional model for intrinsic motivation**

**Kohei Noda**

Kocoro Laboratory Inc.

**Abstract:** The author of this article previously collaborated on the analysis of the process of a coaching session and a motivation training program. Case studies were conducted from those analyses. However, those studies are separate and there is no integrated cognitive model existing to explain the cognitive emotional process of those cases. Also, case studies of entrepreneurs in which the reason they founded their companies have also been conducted. In this study, a cognitive emotional model and intrinsic motivation, a key concept, are introduced and modeled. To model the Knowledge, Skills, Abilities and Others (e.g. traits and etc.)(KSAOs), Human Resource Assessment (HRA) Ontology is introduced. To model human emotion and motivation, Cognitive Emotional Agent Architecture (CEAA) is introduced. A new integrated concept for motivation training courses and coaching sessions is developed based on the developed cognitive emotional model.

# What is the trial-and-error process of design thinking?

**Hisataka Noguchi**

freelance (retired)

**Abstract:** What is the trial-and-error process of design thinking?

Hisataka Noguchi

When we think about design creativity we should recollect the fundamental feature of the design thinking process as this:

- (1) Design thinking is essentially included in general human productive works as a whole.
- (2) Design thinking usually goes not straight to the goal but requires trial-and-error processes in which repetitive divergent and convergent thinking are taken.
- (3) For converging the trial-and-error to goal, designer needs self-evaluations in every step of getting tentative solutions.
- (4) Even though the collective thinking and discussions facilitate this process, creative result can be carried out basically depend on each designer's self-evaluation.

The author tried to make a model of trial-and-error process of design thinking in which one can analyze how the self-evaluations converge the process as a representation of designer's internal world.

# Choosing unknown goods: An fMRI study of product choice

**Ikuya Nomura**

The University of Tokyo

**Kazuyuki Samejima**

Tamagawa University

**Kazuhiro Ueda**

The University of Tokyo / CREST

**Yuichi Washida**

Hitotsubashi University

**Hiroyuki Okada**

Tamagawa University

**Takashi Omori**

Tamagawa University

**Abstract:** Choice between known goods and unknown goods is repeated in everyday life as new products go on the market one after another. Although such choice is one of the key factors of consumer behavior, very few experimental studies have been done thereon. In the present study, repetitive choices among known goods and unknown goods are performed by utilizing mineral water as stimuli and characteristics related to the choice are examined. Further, brain activity during product choice was measured with fMRI. As a result, subjects who had a tendency to seek for information tend to choose unknown goods more and activity in the right frontal pole was observed when unknown goods were chosen. These results indicate that choosing unknown goods is a behavior for the purpose of gaining information but not a consequence of balancing the profits and losses.

# Clarifying position derived from sophisticated beliefs about the nature of knowledge-to-use

Ryota Nomura  
The University of Tokyo

**Abstract:** This study examined students self-reported active clarification of their own and other members position in group discussion in order to shed light on the relation between students beliefs about the nature of knowledge-to-use and their way of participation in cooperative learning. According to their epistemic beliefs, 58 (14 male and 44 female) undergraduate students were assigned to 3 type of groups, including sophisticated (i.e., assuming a wide applicable scope of knowledge and considering prior conditions for application), nave, and mixed. The results demonstrated that students with sophisticated beliefs in mixed-group rated their own clarification higher compared to students with nave beliefs and to students in sophisticated-group. It is discussed that the gap of beliefs provided different ways of argument among students, leading a demand to clarify their stance each other and offering a comparative advantage for students with sophisticated beliefs.

# **A Method of interviewing to Constructively Generate a Narrative through Interactions between Interviewer and Interviewee - A Case Study to Examine Creative Thoughts of an Architectural Student -**

**Haruka Nukariya**

Keio University

**Masaki Suwa**

Keio University

**Abstract:** We discuss both a method of interviewing about an individuals creative thinking and a method of recording an interviewers behavior. From the viewpoint of scientific examination, interviewing is supposed to be an act of retrieving an interviewees thoughts in a raw manner without being influenced by the interviewers viewpoints or intentions. An individuals thoughts are, however, mostly tacit knowledge. Even the individual himself is not necessarily able to externalize it by himself. We argue, rather, that interviewing should be an act of generating a narrative in a constructive manner through active interactions between an interviewer and an interviewee. Based on this paradigm change, we have devised a method of interviewing using a memo tool so that the interaction becomes active. Moreover we have developed a method of recording an interviewers behavior situated in the interaction in order to examine what kind of behaviors make the interaction active.

# **Do children who experience regret make better decisions? A developmental study of the behavioral consequences of regret**

**Eimear O'Connor**

Queen's University Belfast, Belfast, Co Antrim, Northern Ireland

**Aidan Feeney**

Queen's University Belfast, Belfast, Co Antrim, Northern Ireland

**Teresa McCormack**

Queen's University Belfast, Belfast, Co Antrim, Northern Ireland

**Abstract:** To date there has been little research investigating the assumption that experienced regret influences future decision making. Three novel experiments examined the relationship between childrens ability to experience regret and the quality of their subsequent decision making. Children chose between two options on Day 1, discovered the non-chosen option was more attractive, and rated their feelings about their choice. On Day 2, to assess choice switching, children were presented with the same choice. Experiment 1 found regret and adaptive choice switching emerged around 7 years of age. Experiments 2 and 3, found that 6-and 7-year-olds who experienced regret on Day 1, engaged in profitable decision making significantly more often than those who did not experience the emotion. These findings remained even when age and verbal ability were controlled for. These findings suggest that the experience of regret influences similar future decision making in childhood.

# Analysis of Human Solving Process of Constraint Satisfaction Problem

**Hidemi Ogasawara**

Chukyo University

**Yoshiyuki Matsuzawa**

Chukyo University

**Masahide Ogawa**

Chukyo University

**Abstract:** This study discusses cognitive process in solving constraint satisfaction problem in terms of both operation and information acquisition strategies by examining human process data with eye mark tracking solving Sudoku.

Generally a Sudoku problem is defined as a CSP where a cell corresponds to a variable, and its domain of values is a set of the numbers. One of the major inference strategies to solve it is constraint propagation based on local consistency that resolves conflicts within a local variable set, and a problem that is solvable only by resolving the two-variable consistency is classified as "easy".

However, the result of human data does not support this naive problem definition and the strategy. It can be explained by another problem representation where a number corresponds to a variable, and a cell to a domain value. We check the cognitive validity of this representation and the strategies based on it.

# Towards the Development of Integrated Narrative Generation System as the Implementation of Literary Knowledge

**Takashi Ogata**

Iwate prefectural university, Iwate, Japan

**Taisuke Akimoto**

Iwate Prefectural University, Iwate, Japan

**Abstract:** Narrative contains diverse literary elements (e.g. narrator, character, story, plot, media), and narrative generation system should organically combine them. Previously, we developed a variety of the elements comparatively individually. The current goal is to develop a system in which all modules are organically integrated. This paper shows the pilot integrated system including about 800 modules and conceptual dictionaries, moreover discusses a detailed design for the revised version. The generation phase is divided into story, discourse, and expression. Story and discourse are described as each conceptual structure. The transformation by narrative techniques is corresponding to the narrative generation process. The mechanism is constructed by the integration of AI techniques such as script, story grammar, discourse relations and narratological knowledge such as Propps story structure, Genettes discourse theory and Jausss reception theory. In this sense, this system is also an approach integrating the interdisciplinary genres. The generation process is executed by a control mechanism that selects techniques to be used based on the parameters for defining structures and characteristics of the narrative to be generated.

# Effect of Age-related Decline of Task Switching on the Task Sequences that Simulate Real Job

**Keiji Ogata**

Azbil Corporation

**Satoru Suto**

Shizuoka University

**Kazutaka Ueda**

The University of Tokyo

**Takatsune Kumada**

National Institute of Advanced Industrial Science and Technology

**Tohru Ifukube**

The University of Tokyo

**Abstract:** Task switching is an important cognitive function when older adults work using ICT equipment. We focused on properties of older adults task switching function in order to design usable ICT equipment. Generally, a worker has to execute some tasks serially by switching them reciprocally. In this study, some sequences such as AB, AAB, or AAAAB were taken into consideration because there are routine tasks and rare tasks. Participants were 24 older adults and 24 younger adults. Reaction times and switch costs of various sequences were analyzed. As the result, although switch costs for older adults were heavier in AAB than AB, the switch costs did not increase for longer repetition of A (i. e., AAAB and AAAAB). The heaviest switch cost was seen in AAB when A was a difficult task and B was an easy task. These results were different from those of younger adults.

# **Rhetoric of Biopic and Viewer's Reconsideration : Isnt story an Obstacle?**

**Yukiko Ogawa**

HOSEI University

**Akihito Kanai**

HOSEI University

**Abstract:** In the cognitive process when the viewers of narrative moving images appreciate its world and to deepen their consideration, is it story or rhetoric to take an important role? This is the interdisciplinary point at issue cross-linking the domain where study such as art, literature, rhetoric, and a problem of representation with images, and a cognitive-affective mechanism are connected. Therefore this study used two biopics - "Tower of TARO" and "YUMEJI", and examined it. After having shown the 10 minutes partial images which experimenters fixed, the questionnaire was performed for 267 participants. The question was given "how you reconsidered the concept that experimenters showed to watch each image". Free variables were made by the answers about disposition to various images, ANOVA was carried out afterwards. As a result, it was suggested that the deep concept reconsideration might occur more towards the viewers which minded rhetoric than story development.

# Developmental Adjustment of Iconic Language in Care-Takers' Input

**Masato Ohba**

Tamagawa University

**Noburo Saji**

Keio University / JSPS

**Mutsumi Imai**

Keio University

**Tomoko Matsui**

Tokyo Gakugei University

**Abstract:** This study explores how care-takers use mimetics -a word class which has a clear sound symbolism- in communicating with their children to investigate the role of iconicity in the input for language development. We approached the question by combining a study of mother-child interaction corpus and a Child-Directed-Speech elicitation experiment, in which care-takers were asked to describe animated actions first to their child and then to an adult experimenter. The results showed that care-takers use mimetics more frequently and use them alone as interjections without embedding them in a sentence for younger children. As their child develop care-takers begin to use mimetics adverbially in a sentence, as they do in Adult-Directed-Speech. This change suggests that care-takers adjust the degree of iconicity in the input according to the child's developmental stage, from bare use to syntactically embedded use of mimetics, and then eventually to non-mimetic conventional words.

# Effects of Language on Asynchronized Audiovisual Speech Perception

**Hitoshi Ohnishi**

The Open University of Japan

**Kaname Mochizuki**

Teikyo University

**Abstract:** When people are exposed to asynchronized audiovisual speech, they feel that something is unnatural. We performed tests to determine whether the language used in audiovisual speech affected the observer's perception. In experiment 1, we examined whether Japanese native speakers were more sensitive to audiovisual asynchrony in Japanese audiovisual speech than in English audiovisual speech by using simultaneity judgment tasks. Results showed that the language had no effect on sensitivity to audiovisual asynchrony. In experiment 2, we examined whether audiovisual asynchrony affected the observer's perception of loudness. Results showed that the observer perceived a voice to be quieter when the speaker's face moved after the speaker had spoken. This effect was weaker when the reverse was true and the speaker's face moved first, followed by the speaker's voice. Moreover, the effect was also not as strong when Japanese native speakers observed asynchronized audiovisual speech in English as opposed to Japanese.

# **The effects of regularity in spatial inferences with and without local landmarks on spatial learning**

**Kayoko Ohtsu**

Waseda University

**Yoshihiro Ouchi**

Teikyo-Gakuen Junior College

**Abstract:** Regularity in spatial inferences during wayfinding has a different effect on spatial learning depending on clues available in an environment. Our previous study has revealed that the irregular updating, which involves multidirectional self-to-object updating, has a facilitation effect when global landmarks are available, while it impedes the learning without the landmarks. In the present study, we examined the updating mode in the context of local landmark information. In the experiment using a real maze, participants visited multiple targets in one of four conditions by a combination of two factors: an updating mode (regular or irregular) and an environmental information mode (with or without local landmarks). The results suggest that there is an interaction between factors. Although there is no difference between three of the conditions (regular & landmarks, regular & no landmarks, and irregular & landmarks), the irregular updating impedes the learning without the landmarks.

# Computational model of the meaning acquisition of sentence-final particles

**Natsuki Oka**

Kyoto Institute of Technology, Kyoto, Kyoto, Japan

**Naohiro Nonoguchi**

Kyoto Institute of Technology

**Chie Fukada**

Kyoto Institute of Technology

**Motoyuki Ozeki**

Kyoto Institute of Technology

**Abstract:** Sentence-final particles serve an important role in (spoken) Japanese, because they express the speaker's mental attitudes toward the proposition and/or the interlocutor. They are acquired at early ages and occur very frequently in everyday conversation. There has been, however, little proposal for the computational model of the acquisition of sentence-final particles. The purpose of this study is to get a robot to learn how to act upon the utterance with a sentence-final particle. The robot learns appropriate responses based on the rewards given by the interlocutor. The experimental results show that the robot learns to behave correctly in response to 'yo,' which expresses the speaker's intention to communicate new information, and to 'ne,' which denotes the speaker's desire to confirm that some information is shared. Using the learned actions as a lead, the acquisition of inner information processing such as word learning is the next research target.

# Is the breaking point in mental number line in Japanese children five or ten?

**Masahiko Okamoto**

Osaka Prefecture University

**Sari Nakamura**

Osaka Prefecture University

**Abstract:** The purpose of the present study is to examine that (1) are there breaking points in mental number line in Japanese children, and (2) does it relate childrens calculation performances. The magnitude decision task for eight number pairs, e.g. 3-5, was used in this study. Participants were 40 first graders children. An ANOVA for the decision time revealed that the main effect of number pairs is significant ( $F(1, 39) = 8.45, p < .01$ ). A Tukeys HSD test indicated that the decision time for 4-6 and 5-7 were slower than for 3-5, and the time for 9-11 and 10-12 were slower than for 8-10. These results indicated that there are the five-break and the decade-break in metal number line in Japanese children. And a negative correlation between the decision time and the performances of calculation problem were obtained. It suggested that the calculation skill is acquired based on the mental number line.

# **Influences of a potential interlocutor on the utterances of the speakers who try to describe objects**

**Junji Okamoto**  
Gakushuin University

**Saori Ushiyama**  
Gakushuin University

**Abstract:** Two sets of production tests were conducted in January and February in 2012, both in Tokyo and in Mannheim (Germany) to capture differences of utterances which subjects produced with or without the presence of another person, who sat at 45 deg. left in front of them, remained silent, but pretended to be ready to talk with them. The subjects were requested to describe or comment on objects appearing on the computer display at an interval of 10 sec. Our working hypothesis is that intersubjective expressions such as end-particles in Japanese (JEPs) and modal particles in German (GMPs) would be more frequently observed with the presence of a potential interlocutor. The result was that although the influence was confirmed, GMPs were rarely used even in her presence, while JEPs were frequently used even without her presence. This suggests that there is a crucial difference in terms of interlocutor's commitment.

# **Delay of word order development in Japanese? Evidence from a preferential looking study with 19 and 30-month-old children**

**Akira Omaki**

Johns Hopkins University

**Romy Lassotta**

University of Geneva

**Tessei Kobayashi**

NTT Communication Science Laboratories

**Luigi Rizzi**

University of Siena

**Julie Franck**

University of Geneva

**Abstract:** Word order constitutes a fundamental cue for sentence comprehension. Previous research on English and French found evidence for adult-like word order knowledge in 19-month-olds, but little is known about early word order development in languages with frequent word order alteration and argument omissions that reduce positive evidence for the canonical word order. To address this question, we conducted (i) a distributional analysis of word order variation in child-directed Japanese, and (ii) a preferential-looking study with Japanese 19- and 30-month-olds, using the same design as a previous study on French 19-month-olds. Our analysis of 17726 child-directed utterances revealed that 91% of the input was uninformative for identifying the canonical SOV order. Next, our preferential-looking experiment revealed that Japanese 19-month-olds fail to understand sentences with a canonical word order, unlike French 19-month-olds or Japanese 30-month-olds. We suggest that the sparseness of SOV in the input delays the development of word order knowledge.

# Effects of supraliminal and subliminal hint priming on insight problem solving.

**Ryo Orita**

Graduate School of Letters, Ritsumeikan University

**Masaki Hattori**

Department of Psychology, Ritsumeikan University

**Abstract:** In two experiments, a total of 135 participants engaged in a 10-coin problem for four minutes. Half of them were exposed to a hint figure one time per ten seconds. In Experiment 1, the hint figure was presented for one second, and participants were told that this figure was unrelated to the problem (supraliminal priming). Thus, they were aware of the figure, but they were unaware that it served as a hint. In Experiment 2, the hint was presented for thirty milliseconds, and it was masked by geometric configurations (subliminal priming). This ensured that participants were unaware of the hint. Both types of hint increased the solution rate. These results suggest that the conscious access to the hint is not essential for the priming effects. Exposure to a hint can activate insightful ideas without awareness, and it increases the probability of producing an appropriate strategy to escape from an impasse.

# Transfer of learning from project activities to individual leaning

Naoko Osada

Seisen Jogakuin College

**Abstract:** A number of studies indicate that project-based learning enhances a student's motivation, engagement, and deep understanding. But it is difficult to promote successive individual learning based on the experience of the project. To improve the linkage between the project and the subsequent activities, this study attempted to exploit the context-based approach to enhance the reflection by the students under the design experiment. The results showed that more than half of the second year students successfully used the findings through the project activities to define their individual research theme. Also their final reports were well-organized and the level of the consideration was relatively high than that of the first year. In the real world settings like workplace, it is important to figure out the situations carefully before applying the individual knowledge or skill. Contexts could work as scaffoldings to improve the transfer in the real world.

# **Ranges of storage item sizes in complex working memory span tasks: Latent-variable analysis of the memory load**

**Kazunori Otsuka**

University of Nagasaki

**Makoto Miyatani**

Hiroshima University

**Abstract:** To measure individual differences in working memory capacity, complex span tasks have been developed. These tasks, which predict several aspects of higher-order cognition, have associated ranges of storage item sizes that are regularly controlled to avoid ceiling and floor effects in performance distributions. To examine the memory load incurred by the ranges of storage item sizes, this study used different storage item sizes for complex span tasks across verbal, numerical, and spatial content domains. Particularly examined were the relations among processing, storage, and general fluid abilities of the different storage item sizes of complex span tasks. Results of latent-variable analysis indicate different relations among these components of participants performances in complex span tasks, for which the item sizes differed. The influences on the memory load of storage item sizes of these tasks are discussed.

# **Does the detection of mind wandering require attentional resources?**

**Sho Otsuka**

Graduate School of Education, Tokyo Gakugei University

**Takahiro Sekiguchi**

Department of Educational Psychology, Tokyo Gakugei University

**Abstract:** Individuals can observe the occurrence of mind wandering (task-unrelated thought) while doing an important task and stop it. This study examined whether mind wandering is detected through the monitoring process requiring attentional resources. In the first task, participants read a short story, where the constituent words were presented one-by-one and the next word appeared by pressing a key. The reading time for each word was measured. As a secondary task, one group reported the occurrence of mind wandering each time they noticed it during the reading. The other group performed a prospective memory task (detecting target words) that required attentional resources, and the control group performed only the reading task. The result showed that while performing the prospective memory task increased the mean reading time, the reporting of mind wandering did not influence it. This finding suggests that the detection of mind wandering did not require attentional resources.

# **Analysis of the relationship between writing skills and evaluation in an expository writing assignment**

**Hiroko Otsuka**

Future University Hakodate, Hakodate, Hokkaido, Japan

**Mio Tsubakimoto**

Future University Hakodate, Hakodate, Hokkaido, Japan

**Hiroshi Numata**

Future University Hakodate, Hakodate, Hokkaido, Japan

**Abstract:** Our research aims at acquiring the knowledge to develop an effective system of support for revising written assignments, in order to assist students to compose logical sentences by themselves. We analyzed, quantitatively and qualitatively, the problems that arose in expository writing assignments, and the relevance of grade calculations. Furthermore, we also surveyed student attitudes toward written assignments in order to examine appropriate methods of support in the revision process.

Expository writing texts are composed of a title, a body text, and a bibliography. The body text contains the definition of the theme, the reason for the choice of theme, questions that arise relating to the theme, exploration of these questions, and the conclusions.

Our results demonstrated that the quality of the revised texts was influenced by the following factors: the length of the whole text, the section pertaining to the exploration of the research questions, and the bibliography.

# Loosely symmetric heuristics as the basis for biases and the empirical Bayes methods

**Kuratomo Oyo**

Tokyo Denki University

**Tatsuji Takahashi**

Tokyo Denki University

**Abstract:** The loosely symmetric (LS) model, a conditional probability-like formula describing human symmetric cognitive biases, is shown to be effective in an ample amount of areas including causal induction, learning (reinforcement, supervised and unsupervised), game-theoretical situations and digital game AI. However, despite its interesting mathematical properties, the total rationale for the model has not been given. In this study, we analyze LS from the viewpoint of Bayesian statistics, especially of the empirical Bayes methods. As the result, we show that the bias terms in LS, which deviates LS from the ordinary conditional probability, are the hyper parameters for the prior Beta distribution LS assumes. Given this analysis, LS is shown to describe various cognitive biases including Gamblers fallacy, status quo bias, the framing effect, dependence to the reference point and the reflection effect, etc., all at the same time.

# How simple explanations change our minds and why we prefer them

**Michael Pacer**

UC Berkeley

**Tania Lombrozo**

UC Berkeley

**Abstract:** People prefer simpler explanations and judge them more satisfying, where simplicity is defined as the number of unexplained causes in the explanation (root simplicity). But what are the effects of this preference on cognition and why do people like simple explanations? We consider the answers to these questions with three experiments. Our findings suggest that the participants who select simpler explanations when the simpler explanation conflicts with available data are more likely to overestimate how often they saw data points consistent with their chosen explanation. We show that choosing a simpler explanation causes this data distortion. We find that the preference for root simplicity is stronger when root causes greatly alter the probability of their effects. This aligns with arguments suggesting a preference for root simplicity results from the desire to efficiently encode observations and to support effective interventions. These findings have implications for theories of inference and explanation.

# **The Influence of Culture: Thematic versus Taxonomic Categorization**

**Jo Pan**

National Cheng Kung University

**Gert Westermann**

University of Lancaster

**Hsueh-Chih Chen**

National Taiwan Normal University

**Jon-Fan Hu**

National Cheng Kung University

**Abstract:** There is evidence that cognition processes may not be universal for people in the world. The goal of this study was to explore whether people from different culture backgrounds adopt varied concepts to categorize objects. Participants from eastern and western were required to rate association strength of word pairs in questionnaires which used five-point-scale. Two types of word relations are manipulated. These words were paired by taxonomic (e.g., banana - apple) or thematic (e.g., banana - orangutan) categories. The results showed culture differences. Relative to western people, easterners tend to put weaker emphasis on objects taxonomic categories than on thematic relations. There was an interaction between people from different cultural background and the type of relations. The tendency influenced by culture to sort objects into thematic or taxonomic categories will be discussed in further research.

Keywords: culture, thematic, taxonomic, categorization

# **Do Objects Matter for Infants Formation of a Spatial Category?**

**Youjeong Park**

Cornell University

**Marianella Casasola**

Cornell University

**Abstract:** Presenting a relation using simplified objects facilitates the generalization of that relation in older children and adults (e.g., Kaminski, Sloutsky, & Heckler, 2006, 2008). We investigated infants ability to form a category of a support relation (i.e., on) when the objects that depicted the relation were perceptually simple versus more complex. Fifty-three infants of 8 and 14 months were habituated to dynamic support events with either simple or complex objects. They were then tested with events with novel objects, a novel spatial relation, or both. Infants at each age formed a support category, looking significantly longer at test events with a novel than familiar relation. There was a marginal effect of object complexity. The current results suggest a role of object features in infant spatial categorization, and provide the first evidence that infants of 8 months can form a spatial category of support relations.

# **Cross-level Illusory Conjunction between Implied (Semantic) and Actual (Perceptual) Colors**

**C. J. Park**

Department of Psychology, The University of Hong Kong

**A. W. Y. Ho**

Department of Psychology, The University of Hong Kong

**G. H. T. Tsui**

Department of Psychology, The University of Hong Kong

**J. T. Y. Chan**

Department of Psychology, The University of Hong Kong

**X. Luo**

Department of Psychology, The University of Hong Kong

**C. H. Tseng**

Department of Psychology, The University of Hong Kong

**Abstract:** Goldfarb and Treisman (2010) found observers made more perceptual binding errors (illusory conjunctions, ICs) when the features of an object were inconsistent. They suggested that such mistakes originate from features in the same level. We investigated whether we could induce ICs across perceptual and semantic domains by manipulating the font colour of object words containing implied colours. In Experiment 1, participants saw very brief displays of four Chinese characters ((sun), (fire),(hill), (water)) printed in either yellow, red, green, or blue. Observers had to report the physical color of a randomly selected target word in each trial. We observed significantly higher error rates when the words were printed in colours incongruent with their implied color. We replicated the result with a set of English words (lemon-yellow, water-blue, blood-red, and grass-green) in Experiment 2, which led us to conclude that illusory conjunctions can arise in the gulf between semantic and perceptual domains.

# **Judgment under uncertainty is not always certainty-oriented**

**Youngjun Park**

Ajou University

**Kyungil Kim**

Ajou University

**Abstract:** Previous research of uncertainty has assumed that peoples single time- preference for alternatives is based on the degree of availability in probability. We, however, suggest that the influence of probability decreases when a global strategy includes multiple selections with a single goal. A game, which involves a tournament of 8 teams, is introduced to the participants and they were asked to select 4 teams so that their selection includes the winner. Participants choice responses were classified into 2 types. The first type is to pick all the 4 teams on one side of the bracket (a sure 50% to win) making the degree of uncertainty minimized. The second type includes all other ways of selection, except the first type, with greater uncertainty. The results indicate that only 37% chose the former strategy indicating that the majority of people used a strategy with higher uncertainty.

# The Effect of Perceptual Complexity on Affective Picture Processing

**Taejin Park**

Chonnam National University, South Korea

**Soodam Park**

Chonnam National University, South Korea

**Abstract:** Previous ERP studies using IAPS (International Affective Picture System) pictures have reported several ERP components (e.g., P1, N2, LPP) whose amplitudes are modulated by valence and arousal. But Bradley and her colleagues (2007) reported that early ERPs were modulated only by perceptual complexity, and only late ERPs (LPP) were modulated by affective factors. To elucidate the modulatory effect of perceptual complexity and affective valence of IAPS pictures on ERPs, we manipulated perceptual complexity and valence of them. Pleasant, neutral, and negative pictures from IAPS depicting either simple figure-ground compositions or complex scenes were selected. Each picture was presented for 2 s and participants were required to do valence discrimination response. 30-electrodes ERP data of 28 university students were analyzed. Mean amplitudes of early posterior P1 and P2, and LPP showed interaction effect of perceptual complexity and valence, and showed perceptual complexity effect only for neutral and positive pictures (no perceptual complexity effect for negative pictures). Time-frequency analysis showed similar results: Power of alpha and theta activities showed perceptual complexity effect only before 300ms, and showed the effect only for neutral and positive pictures. These results suggest that early ERPs can be modulated by affective valence and perceptual complexity only for neutral and positive pictures, and valence effect of negative pictures might override the effect of perceptual complexity.

# Effect of Saliency-Based Masking in Scene Classification

**Tae-Suh Park**

Seoul National University

**Byoung-Tak Zhang**

Seoul National University

**Abstract:** In this paper, the effect of attention-based local feature selection to 15-class scene classification is investigated, as an extension of the previous researches showing the different effect of each spatial scale to its performance in the early stage of human vision processing. Visual saliency is used as a criterion for selecting the local regions from where HoG features are extracted. Experimental results show that such saliency-based masking significantly affects the classification performance: contrary to the previous reports in the field of object recognition, the low-salient regions contribute more than the high-salient regions in scene classification, and that is consistent with several previous reports of insisting the importance of spatial layout in the low frequency channel, which support the scene schema hypothesis. Also, the result implies that the highest salient regions, which occupies top 20 percent in saliency, hardly contribute to classification performance.

# **fMRI evidence for sensitivity to coherence and context in the theory of mind network**

**Alexander Paunov**

Massachusetts Institute of Technology

**Jorie Koster-Hale**

Massachusetts Institute of Technology

**Rebecca Saxe**

Massachusetts Institute of Technology

**Abstract:** Much neuroimaging work converges on a set of brain regions engaged in representing the mental states of other agents. These regions, the theory of mind (ToM) network, include the bilateral temporoparietal junction, dorsomedial prefrontal cortex, and precuneus. Studies employing diverse methodologies consistently reveal greater activation in the ToM network to stimuli that prompt mental state attribution relative to various control conditions. However, attempts to elicit differential responses within the network by manipulating mental state content have typically failed. We report findings that the network is sensitive to two features of mental state stories. First, the hemodynamic response is reduced following a coherence break in the stories plot relative to a coherent condition, in both ToM and left-hemisphere language areas. Second, the amount of context provided is positively related to the strength of activation in the network. These results suggest that ToM representation depends on a sustained input of coherent information.

# **The Role of Linguistic Knowledge in Hue Perception**

**Katherine Phelps**

University of Colorado, Boulder , CO, United States

**Steve Duman**

University of Colorado, Boulder

**Kevin Gould**

University of Colorado, Boulder

**Les Sikos**

Swarthmore College, Swarthmore, PA

**Abstract:** It has been argued that real-world structure constrains the semantic representations of verbs, resulting in cross-linguistic convergence of naming patterns for motion events. This study explores the nature of this real-world structure by manipulating individual features of human locomotion in video stimuli and comparing the responses of English and German speakers in an elicitation task. We show that individual features influence naming patterns and that languages encode these features differently. Furthermore, the semantic representations of several German motion verbs sharply contrast with their English equivalents.

# **fMRI of attention and automaticity in judgments from facial appearance**

**Ramsey Raafat**

**Nick Chater**

University of Warwick, Warwick Business School

**Abstract:** Facial social judgments such as trustworthiness, indeed the processing of facial and emotional stimuli are fast (Bar, 2006) and are often proposed to take place in an automatic fashion, that is independent of top down factors such as attention (Jonides 1983). Here we present work that challenges the automaticity account of such judgements.

In a series of experiments we apply load theory (Lavie, 1995, 2010), to investigate subjective judgements under load. Employing a combined visual search and face judgement task, where the level of attentional load in the search task was manipulated (by varying the search set size) the results indicated reduced accuracy for trustworthy judgements under the effects of attentional (perceptual) load. Finally, in a neuro-imaging task (that is a pure signal response to facial stimuli) we again illustrate the effect of load, where high load modulates (at a neural basis) trustworthy faces.

# **Cooperative Behavior in Multicultural Settings: The Contribution of Altruistic Punishment**

**Abstract:** In this study we want to explore the behavior of altruistic punishment, investigated through the Third Party Punishment game. This game shows the behavior of spending ones own money, without any personal benefit, to punish unfair behavior of players who violate cooperation norms. This behavior may be differently displayed depending on the in-group versus out-group setting, and typically favors ones own group (the so called parochial altruism). We compared two different cultural groups: Italian (N=26) versus Chinese people (N=26). In both groups, our results show the presence of altruistic punishment behavior, and this tendency emerges much prominent when facing another groups player who behaves unfairly with ones own group members. Furthermore the whole sample shows the propensity to spend little sums of money to punish also fair behaviors: this attitude is known as antisocial punishment. Our data also show that Italians spend significantly higher amounts than Chinese for antisocial punishment.

# **Why so Stressful? The effect of coping strategies and social support to undergraduate students in Korea**

**Young Sun Ryu**

Seoul National University

**Ha Rim Kim**

Seoul National University

**Jeong Ryu**

Seoul National University

**Abstract:** Purpose: To investigate the amount of stress that Nursing College Students for Nursing Examination acceptance competitions and campus life. Method: The data was collected from 250 students at S Nursing College in Seoul, Korea using questionnaires including the following: CES-D(Center for Epidemiologic Studies Depression), BAI(Beck Anxiety Inventory), Coping Stress Scale, Self Esteem Scale, Social Support. Results: The average score for the CES-D turned out to be 18.43(SD: 7.25) which higher than the average 14.77(SD: 9.47) which was firefighters in Seoul, Korea who had experienced many kinds of disasters. As a result, the mediating effects of positive emotion on the relationship between the social factors and CES-D /BAI were supported. CES-D was positively related only to social support( $r = 6.47$ ,  $p < .000$ ) and especially, CES-D most related family support which one of the social support and didnt any relationship with the amount of other scales. Conclusions: We must acknowledge the fact that the amount of stress being received by college students preparing for Nursing Examination is very severe. The amount of stress was even higher than that of college students who experienced a natural disaster. There should be active programs in Nursing College to alleviate this stress if we want to have brighter, healthier college students in the future.

# Automatic Reverse Engineering of Human Behavior Based on Text for Knowledge Acquisition

**Rafal Rzepka**

Hokkaido University, Sapporo, Hokkaido, Japan

**Kenji Araki**

Hokkaido University, Sapporo, Hokkaido, Japan

**Abstract:** We propose a novel approach for building cognitive architectures based on Wisdom of Crowd. As knowledge needed for an intelligent system is difficult to gather and heavily depends on a programmer's bias, we decided to automatize the process of surveying reactions, decisions, opinions, etc. For demonstrating the usability of our approach we implemented Web-mining functions into our system and tested it by confronting with over 100 ethically-significant real world problems, e.g. "killing a man", "stealing money", "bribing someone", "helping people" or "saving environment". The accuracy was 86% when used emotional consequences discovery, however we show how adding social consequences discovery, natural language processing tools and bigger data sets are able to refine the results and increase correctness of moral judgment. We discuss the importance of such algorithm based on crowd behavior, which opens a path for retrieving universal transcultural rules when the system becomes multilingual and compares results from different nations.

# **The Internal Structures of Sound-Symbolic Systems: the Universal and Language-Specific Portions of Sound Symbolism**

**Noburo Saji**  
Keio University/JSPS

**Kimi Akita**  
Osaka University

**Mutsumi Imai**  
Keio University

**Katerina Kantartzis**  
University of Birmingham

**Sotaro Kita**  
University of Birmingham

**Abstract:** This paper demonstrates a new quantitative approach to identify what is behind universally sensed sound-symbolism and sound-symbolism detected only by speakers of a particular language. For this purpose, we presented 70 locomotion videos to English and Japanese speakers and asked them to create a word that would sound-symbolically match each action. Then the participants rated each action on 6 semantic dimensions. Multivariate analysis detected what level of sound-unit (e.g., phonetic features, phoneme, mora) are linked to each semantic dimension. Results revealed that certain sound-meaning links (e.g., voicing and heaviness) are more consistent than others within and across languages. Furthermore, language-specific sound-symbolism was found in the particular sound-units (e.g., the sequence of a voiced initial consonant and a middle-low vowel and heaviness in English). This implies that the language-specific sound-symbolism is motivated by the phonological system each language possesses, whereas universal sound-symbolism appears at the more abstract level of sound component.

# **Does word order influence non-verbal event description by speakers of OS language?**

**Hiromu Sakai**

Hiroshima University

**Takuya Kubo**

Hiroshima University

**Hajime Ono**

Kinki University

**Manami Sato**

Hiroshima University

**Masatoshi Koizumi**

Tohoku University

**Abstract:** Goldin-Meadow et al. (2008) examined whether word orders of speakers own languages influence their non-verbal behaviors by asking speakers of English, Chinese, Spanish, and Turkish to describe events non-verbally using gestures. They found that speakers of all four languages preferred to perform gestures in Actor-Patient-Action order. Although they argued that this reflects a natural order of event description for humans, their research is limited in languages with Subject-Object (SOV or SVO) word order. In order to verify their claim, we examined Kaqchikel, a Mayan language spoken in Guatemala, employing Object-Subject (VOS) word order. In our non-verbal event description experiment, 32 Kaqchikel native speakers described 18 pictures of transitive events using gestures. We found predominant Actor-Patient order (86.2%) as well as Patient-Actor order (13.8%). These results revealed that event descriptions are not only governed by universal conceptual preference to Actor-Patient order but also influenced by word orders of speakers own languages.

# Embodied Skill to Activate Communication in TV Shows

**Rui Sakaida**

Keio University

**Masaki Suwa**

Keio University

**Abstract:** How can we activate communication? Although we participate in and contribute to various conversations everyday, we are not necessarily self-aware of what skills we employ to activate conversations. A good example of experts good at activating conversations is comedians. They quickly grasp what roles they are supposed to play in any changing circumstances in a TV variety show so that the whole atmosphere is enjoyable. Focusing on Ametalk, a popular Japanese TV variety show, we examined what skills comedians possess to direct conversations toward an enjoyable atmosphere. We analyzed conversations statistically from the viewpoints of roles and rhetoric, clarifying why comedians conversation makes us amused. Especially, our focus is on a popular comedian Mr. Kendo Kobayashi; we statistically showed that he not only makes an appeal of his strong personality by playing some roles he is good at playing, but also changes roles according to circumstances.

# Collective decision-making processes in online social networks

Yasuaki Sakamoto

Stevens Institute of Technology

**Abstract:** How do users process the vast amount of information available online to form opinions and make decisions? To answer this question, I analyzed individual and collective decision-making processes in a social media website, Digg. The results from behavioral experiments and computer simulations indicate that some users make decisions by following the choices of others. In particular, I found evidence of three types of following behavior: following the opinions of the whole community, following the opinions of specific individuals, and reciprocal following of pairs of users that could contribute to the emergence of collective decisions in online communities. The results further suggest that knowing others' opinion about a piece of information affects a user's decisions to follow the opinion but not her perception of the information. I conclude by discussing the implications of this work for predicting trends as well as for using and designing social media websites.

# **Innovating scuba diving education through enhanced immersion and authenticity within the eDiving environment**

**Ron Salden**

Madeira Interactive Technologies Institute, Funchal, Madeira, Portugal

**Abstract:** While recreational scuba diving is considered safe and easy to learn, people often become divers on vacation without frequent follow-up diving. Infrequent diving is ill-advised since the scuba diving skills deteriorate over time which can lead to diving accidents. We aim to address the gaps between diving activities by giving people the opportunity to practice relevant scuba diving skills at home. Although prior work on interactive e-learning environments has shown beneficial learning through adaptive personalized instruction, a missing element concerns physical education. As such, we will add two immersive technologies to enhance the authenticity within the interactive eDiving simulator (<http://www.ediving.us>). For each technology we will run a laboratory and a field study, followed by a field study combining both technologies and using Open Water students. As such, our work not only can improve scuba education but also avoid deterioration of important scuba diving skills and consequently reduce diving accidents.

# **What is promoted by imitation, what promotes imitation: Relation to understanding of others mental states**

**Wakako Sanefuji**

Osaka University

**Tomoka Yamamoto**

Osaka University

**Ikuko Mohri**

Osaka University

**Masako Taniike**

Osaka University

**Abstract:** Infants are more likely to imitate actions on objects than body movements (Rogdon & Kurdek, 1977). A recent developmental theory assumes the relationship between body imitation and understanding of others mental states such as intention (Meltzoff, 2004), but there are few evidence on such relationship. The present study was aimed to reveal the developmental linkage between body imitation and understanding of others intention in infancy. Twenty-two participants visited longitudinally at 13, 15, and 17 months of age. We conducted imitation tasks (object manipulations, gestures, and non-meaningful actions) at 13 and 17 months, and task of understanding of others intention at 15 months. Results showed a developmental path from imitation (non-meaningful actions) at 13 months to understanding others intention at 15 months, and also from understanding others intention at 15 months to imitation (gesture and non-meaningful actions) at 17 months. The relationship between imitation and understanding others intention will be discussed.

# Conditions that Modulate Perceptual Interference

**Ava Santos**

Fort Lewis College

**Lawrence Barsalou**

Emory University

**Christy Wilson**

Northeastern University

**Abstract:** Perceptual interference refers to less accurate memories due to verbalizing or imaging nonverbal experiences. We theorize that this occurs because people have prototypical representations of nonverbal stimuli, and these prototypical representations are activated when they verbalize or image exemplars of the stimuli. The activation takes place even though the prototype and the exemplar differ. When people are prompted to remember the exemplar, they mistakenly remember the prototype. In the present study, we want to identify conditions that modulate perceptual interference. We hypothesize that verbalizing nonverbal stimuli multiple times, in the absence of the actual stimuli, will increase the perceptual interference effect. We also hypothesize that viewing nonverbal stimuli multiple times will decrease the perceptual interference effect. Our sample consists of 48 students from a private Southern university and members of the surrounding community. Our hypotheses are supported, demonstrating that there are conditions that can affect the strength of perceptual inference.

# **Contribution of the positive emotional sounds to upward vection**

**Kyoshiro Sasaki**

Kyushu University, Fukuoka, Japan

**Takeharu Seno**

Kyushu University, Fukuoka, Japan

**Yuki Yamada**

Yamaguchi University, Yamaguchi, Japan

**Kayo Miura**

Kyushu University, Fukuoka, Japan

**Abstract:** We examined the effect of positive sounds on upward self-motion perception (vection). Observers listened to positive (e.g., a baby's laughter) or neutral (e.g., a sound of helicopters propeller) emotional sounds during viewing a large vertically moving sinusoidal luminance-defined grating (78 deg 62 deg). The results showed that the upward vection was enhanced by the positive emotional sounds, but not the neutral emotional sounds. This might be because positive affects are linked with spatial/directional up in our mind.

# Surmising of location with vague embodied agents instructions

**Ryo Sato**

Shizuoka University, Hamamatsu, Shizuoka, Japan

**Yugo Takeuchi**

Shizuoka University, Hamamatsu, Shizuoka, Japan

**Abstract:** In this paper we investigate whether joint attention should be achieved between a human and a vague embodied agent by conducting an experiment. Joint attention plays an important role in making conversation smoothly and fulfilling sympathy for each other. And the effect of joint attention has been proved between humans and agents. In this experiment, humans are directed their attention to the certain location by agents instructions consisting of demonstrative pronoun. We made observations of the special relation between human and agent, and the human responses to the agents instructions. What the vague embodied agent is a sphere like bowling ball and its appearance doesnt show where its attentions are turned makes people be unknown its directivity of attention. The result shows that its possible to achieve joint attention between human and the agent even if the agents appearance is too simple and doesnt show where its attentions are turned.

# Looking at nothing facilitates memory retrieval

**Agnes Scholz**

Chemnitz University of Technology

**Katja Mehlhorn**

Carnegie Mellon University

**Josef Krems**

Chemnitz University of Technology

**Abstract:** People fixate on blank locations if task irrelevant visual stimuli previously occupied that region of space. This so-called looking at nothing phenomenon has been associated to information retrieval from an integrated memory representation. However, it is unclear, whether it directly affects the retrieval of information from memory. To clarify this, 23 participants listened to four sentences, each associated to one of four areas on the screen. Subsequently, they had to verify an auditorily presented statement about one of the sentences, by retrieving the related information from memory. During retrieval, participants could either gaze freely, or had to look at a fixation cross that appeared in the area associated to the tested sentence or in one of the other three areas. This manipulation of eye movements significantly affected retrieval performance. The results conform to a grounded perspective on the looking at nothing phenomenon.

# Does Talking to a Robot in a High-Pitched Voice Strengthen an Attachment?

**Ryoko Shibata**

Kyoto Institute of Technology, Kyoto-city, Kyoto-fu, Japan

**Yuki Hachikura**

Kyoto Institute of Technology, Kyoto-city, Kyoto-fu, Japan

**Motoyuki Ozeki**

Kyoto Institute of Technology, Kyoto-city, Kyoto-fu, Japan

**Natsuki Oka**

Kyoto Institute of Technology, Kyoto-city, Kyoto-fu, Japan

**Abstract:** When adults talk to infants, they tend to use infant-directed speech (IDS) rather than adult-directed speech (ADS). IDS is considered to draw the infants attention more than ADS, to convey adults emotional states to infants more easily, and to make language acquisition easier for infants. It is not clear, however, whether the use of IDS has some effects on the adults as well as on the infants. In this research, we focused on one of the most distinctive features of IDS, a high-pitched voice, and conducted two human-robot interaction experiments to examine whether or not the use of a high-pitched voice by the participants him/herself can create a good impression of the robot in their minds. The results showed that the participants in our experiments seemed to be more favorably impressed with the robot when they used a high-pitched voice.

# **An explanation for status of listening to the late musical works of Morton Feldman by cognitive point of view**

**Takuro Shibayama**

Tokyo Denki University

**Tatsuji Takahashi**

Tokyo Denki University

**Abstract:** Abstract: Late musical works composed by Morton Feldman (1926-1987) have common characters, 1) a denial of the development by musical form, 2) a continuance of tranquility and monotonous texture and 3) very long duration of performance. When listening to these pieces, the listeners will just face to the each note rather than trace the musical form brought by the evaluation of result made by listener's expectation to the next musical scene in succession. Shono defines this status of listening as the process that listeners find out the meaning in each note actively, rather than understand the given meaning passively (Shono, 1991). In this study, we explain that the status of this listening are arisen by, a) forfeiture of figure and ground of time sensation, b) activation of multi and inter sensation by the forfeiture of figure and ground, and c) generation of ambiguity between listeners and musical work as an object.

# **A tool supporting conflation of video and picture for physical expression**

**Satoshi Shibuya**

Tokyo Denki University and Future University Hakodate

**Ken-ichi Kimura**

Future University Hakodate

**Abstract:** In this research, an iPad application was developed as a tool promoting physical expression. This tool can create a video picture having a unique story by conflating the pictures that a user drew to the video that one's body action was recorded. In physical expression, by repeating getting a sense by moving a body and giving meaning for that sense, it is necessary to clarify what one want to express. Placing one's physical movement in a story for oneself, it can promote to give concrete meanings for the physical movement therefore it can be useful exercise for the expression. By intuitive touch operation, this tool can perform from recording a body action to drawing the picture and making of the video picture conflated with the pictures. Therefore this tool is aimed at utilizing in physical expression workshops for apprentices.

# Narrative Blending and Tense Aspect by Learners of Korean as a Second Language

Eunji Shim

Sogang University, Seoul, Korea

**Abstract:** As reported in Shim (2011), advanced learners of Korean as a second language (L2) mostly produced background information by using various tense markers while foreground was dominantly described in past tense by learners of low proficiency. Why would proficient learners largely produce background information? This question is addressed in my paper. Unlike foreground, background information must include a description as well as views from an objective perspective, including a commentary and an explanation. It is suggested that, within the framework of Fauconnier and Turner (2002, 93-94), the perspective of the speaker as a writer in a mental space must be linked and blended with that of the other in another space by the Change and the Identity vital relations, and that the blending must be learned by the L2 learners. Viewed from this blending account, productivity of background is likely to be associated with sensitivity of these vital relations

# Reassessing the motivation effect of illustrations in text comprehension

Hideaki Shimada

Shinshu University

**Abstract:** Suppose that you find an article including an illustration that looks interesting, you might read it. My collaborator and I call this phenomenon the motivation effect of illustrations. We proposed an experimental method to evaluate the motivation effect of instructional manuals. In this method, participants were allowed to glance at one manual page for two seconds and were then asked to answer the following two questions: (a) Did the page motivate you to read? and (b) Did the page look easy to understand? The method was utilized to demonstrate that illustrations enhanced participants motivation for reading. But, in this previous study, participants glanced at the same stimuli twice or more in a single experiment, so the procedure could skew the motivation effect. The purpose of this study is reassessing the motivation effect of illustrations when the said problem is improved. As a result, findings of the study prove the validity of the motivation effect of illustrations.

# Brain activity during observation of others action in live and delayed video-mediated social interaction

Sotaro Shimada  
Meiji University, Japan

**Abstract:** Social interaction is largely facilitated by spatiotemporal contiguity among individuals. The brain area called the mirror neuron system (MNS), which is activated when an individual observes the actions of others, as well as when they perform the same action themselves, is considered to play a crucial role in social cognition. The present study investigated whether and how the MNS activity is influenced by temporal contiguity between the observer and observee: (1) live face-to-face, (2) live video-mediated, (3) 6s-delayed video-mediated, and (4) prerecorded action observation conditions. ANOVA revealed that there was a significant modulation by the conditions. MNS activity in the live face-to-face condition was significantly larger than that in the prerecorded condition. A moderate activity was observed in the live and 6s-delayed video-mediated conditions. These results indicate that MNS activity is sensitive to the temporal contiguity, which likely affects the quality of social interaction.

# Many faces of diagrams: from general properties to practical advantages and disadvantages

Atsushi Shimojima  
Doshisha University

**Abstract:** Research on diagrammatic representations has revealed that they, as opposed to sentence-based representations, have the following general properties:

(1) Expressing a certain set of information results in the expression of consequential information (e.g., Barwise & Etchemendy 1990), (2) Certain sets of information cannot be expressed alone, without the (at least selective) expression of other, non-consequential information (e.g., Stenning & Oberlander 1995), (3) Certain inconsistent sets of information cannot be expressed (e.g., Barwise & Etchemendy 1994), (4) Information of multiple levels of information can be expressed simultaneously and relatedly (e.g., Pinker 1990, Cleveland 1994).

There has been an attempt to explain the cause of these properties in a unified manner (e.g., Shimojima 2002). This presentation will focus more on their consequences, specifically, the resultant advantages and disadvantages in the actual uses of information graphics. Examples will be taken from newspaper, magazines, TV news shows, and other popular forms of information media.

# Learning Grammar via Statistical Mechanism

**WonJae Shin**

University of Notre Dame, Notre Dame, Indiana, United States

**Kathleen Marie Eberhard**

University of Notre Dame, Notre Dame, Indiana, United States

**Abstract:** Adults' learning of grammatical dependencies was investigated with an artificial language consisting of shapes (e.g., circles, squares, etc.) and a novel prediction task. The grammar yielded simple sentences and complex sentences with an embedded clause resulting in a non-adjacent agreement relation. Similar to Elman's (1993) Simple Recurrent Network (SRN), sentences were concatenated and presented one shape at a time to participants, who predicted the next shape while the preceding seven shapes remained visible. The sentences represented a staged learning condition, with simple occurring before complex, or a mixed condition with simple and complex randomly ordered. Like the SRN, the participants' token predictions were frequently incorrect; however, accuracy was assessed by whether their prediction was grammatical. Accuracy was above chance in both the staged and mixed conditions demonstrating the beneficial effect of prediction errors, and it was significantly higher in the staged condition, where the stronger local contingencies facilitated category learning.

# **Can you see things from your opponents point of view? – The relationship between critical thinking dispositions and the ability to articulate views different from ones own**

**Noriko Shingaki**

Seijo University

**Yukie Tsuzuki**

Seijo University

**Abstract:** Citizens today are increasingly called upon to critically examine current social issues from different points of view and to engage in public debate about them. Accordingly, training in critical thinking and debate is an important part of Japanese college education. In this study, 72 college students were given a newspaper article about homeless patients being "dumped" by hospitals in Los Angeles. The article was sympathetic to the patients. The students were then asked to comment on the situation from a "neoliberal" standpoint that stressed the value of competition. While 56 students had no difficulty arguing from the alternative standpoint, 16 students were unable to do so and disparaged the hospitals' immoral behavior. The latter group scored significantly lower on the "need for cognition" scale. Protocol analyses revealed that this group had trouble setting their own opinions aside when tasked with articulating views different from their own.

# Magic props induce misdirection differently from the magicians face

**Marie Shoda**

The University of Tokyo

**Kazuhiko Yokosawa**

The University of Tokyo

**Abstract:** Successfully conducting a magic performance requires that the magician guide the gaze of the audience away from the trick towards the props, which is known as misdirection. The role of the social cue, the direction of the magician's face, has been overestimated and the role of the props has been ignored until recently. We contested this assumption by using context congruent props, e.g., cards. Participants observed the same magic show twice. During the second observation, there was a mask on the magician's face, or on the prop, or there was no mask. The prop and the face independently caused misdirection during the second observation, implying that the social cue was not the only factor causing misdirection. It is suggested that top-down knowledge gradually modified the misdirection by inhibiting the fixation on the prop. We conclude that sufficient time is needed to activate top-down knowledge to cancel the misdirection.

# **Infants form expectations about others' emotions based on context and perceptual access**

**Amy Skerry**  
Harvard University

**Mina Cikara**  
Massachusetts Institute of Technology

**Susan Carey**  
Harvard University

**Elizabeth Spelke**  
Harvard University

**Rebecca Saxe**  
Massachusetts Institute of Technology

**Abstract:** Infants attend to and discriminate between other people's emotional expressions. However, it is unknown whether infants have a conceptual understanding of others' emotions and the contexts that elicit them, or merely a perceptual schema for emotional facial expressions. Using a violation of expectation paradigm, we tested whether 11 month old infants expect others' emotional reactions to be contextually congruent. Specifically, infants saw one adult (Observer) react to another adult's (Target) emotional expression. If the Observer was looking at the Target, infants expected the Observer to react congruently (positively to a happy Target, negatively to a sad Target), and looked longer at incongruent emotional reactions. Infants had no expectation of congruence if the Observer was looking away from, and could not see, the Target. This result suggests that within the first year of life, infants represent emotions in terms of the contexts that elicit them.

# **The conflict response of charitable donations on various decoy options**

**Masashi Soma**

Rikkyo University

**Itzuki Chiba**

Rikkyo University

**Yuichi Hasimoto**

Rikkyo University

**Abstract:** The purpose of this paper is to demonstrate to diminish conflict response on charitable donation by multiplying decoy option(attraction,compromise,phantom) in 2 attribute 3 option decision making. Rubaltelli & Agnoli(2011) composed 2 attribute 3 option decision making in donated victim and indicated that a conflict response had been diminished by decoy options(attraction effect). We demonstrate to decoy effect by using Rubaltelli & Agnoli(2011)s task.

# **A Neuro-Robotics Model for the Acquisition of Higher Order Concepts in Action and Language**

**Francesca Stramandinoli**

Plymouth University

**Davide Marocco**

Plymouth University

**Angelo Cangelosi**

Plymouth University

**Abstract:** Recent neurophysiological experiments have shown that motor neurons responsible for encoding specific motor acts present different activation patterns according to the final goal of the action sequence in which that particular motor act is embedded (Fogassi et al., 2005). This is consistent with the chain model hypothesis (Chersi et al., 2006) according to which the processing of action-related sentences involves the activation of the sequence of motor neurons (chain) directly involved in the sentence.

We have developed a cognitive robotic model for the learning of compositional actions from combination of motor primitives. This model uses recurrent neural networks. Simulation results have shown that motor primitives have different activation patterns according to the actions sequence in which they are contained. These results suggest that the motor chain hypothesis (Chersi et al., 2006) can be a general mechanism that explains the way in which recurrent networks represents and reuse hierarchical concepts.

# Representational Translation with Concrete and Virtual Models in Organic Chemistry

**Andrew Stull**

University of California, Santa Barbara, California, United States

**Trevor Barrett**

University of California, Santa Barbara, California, United States

**Mary Hegarty**

University of California, Santa Barbara, California, United States

**Abstract:** Organic chemists must understand the 3-D structure of molecules and be adept at relating different 2-D diagrammatic representations of molecules. Concrete (3D) models can aid chemistry students in developing these aspects of representational competence. A growing trend is to incorporate 3D virtual models into instruction. In two studies, we tested the relative effectiveness of concrete and virtual models when relating molecular representations. Participants completed tasks that involved matching either virtual or concrete models to three different types of molecular diagrams. There were no differences in accuracy for virtual and concrete models, but participants performed significantly faster with virtual models. The benefit likely resulted from the hand-held computer interface, which constrained interactivity to make the most task-relevant information salient. These results highlight the importance of interface design in promoting effective use of spatial representations, and suggest a potential benefit of teaching with virtual models rather than traditional media in chemistry.

# Language and Number Sense: ANS Representations for 'Most'

**Yasutada Sudo**

MIT

**Hadas Kotek**

MIT

**Michelle Fullwood**

MIT

**Martin Hackl**

MIT

**Abstract:** Quantificational expressions ('every', 'most', etc.) afford speakers the means to convey information about the quantity of entities pertinent to a conversation. Their formal linguistic properties have been studied in great detail (Barwise & Cooper 1981, etc.). However, little is known about how they are mapped onto cognitive representations of quantity in particular, to what extent that mapping is determined by their linguistic properties. We present evidence from a series of experiments concerning the quantifier 'most' and argue that 1) it is, as a default, mapped onto representations of the Approximate Number System (ANS) rather than the precise numbers (cf. Lidz et al. 2011); and 2) the mapping reveals cognitive correlates of the complex internal structure of 'most', which encompasses a superlative operator as well as a gradable predicate MANY expressing measure function of quantity (Hackl 2009, Kotek et al. 2011).

# **A left cerebral hemispheres superiority in processing spatial-categorical relation in a non-verbal semantic format.**

**Takashi Suegami**

University of Oslo

**Bruno Laeng**

University of Oslo

**Abstract:** It has been shown that the left and right cerebral hemispheres (LH and RH) have preferences for processing qualitative (or categorical) and metric (or coordinate) spatial relations respectively. However, categorical spatial information could be divided into semantic- and visuospatial-categorical information. We examined whether semantic- and visuospatial-categorical information were different, and whether such a distinction was differentially lateralized. We manipulated the colors and positions of the standard traffic light sign so that either the semantic- or visuospatial-categorical information changed in a non-verbal format and used these stimuli in a sample-to-match task coupled to the divided visual field method. In the semantic-categorical matching task a LHs advantage for processing semantic-categorical information was observed even in a non-verbal format. In the visuospatial-categorical matching task, however, neither left nor right visual field advantage was obtained. These results suggest the processing of semantic-categorical information is lateralized in LH and it is distinct from visuospatial-categorical information.

# **What role do you play in group activity? Objective evaluation through third parties**

**Noriko Suzuki**

Japan Society for the Promotion of Science/Doshisha University

**Tosiro Kamiya**

Osaka University

**Ichiro Umata**

NICT

**Sadanori Ito**

NICT

**Shoichiro Iwasawa**

NICT

**Mamiko Sakata**

Doshisha University

**Katsunori Shimohara**

Doshisha University

**Abstract:** Our daily life provides us a lot of opportunities to participate at work, learn and play with our peers: group learning in schools, training courses in the company, and even outdoor activities. The interactive roles of leaders and followers sometimes emerge and reorganize in our group activities. This study revealed both verbal and non-verbal cues for expressing emergent interactive roles in group activities. Objective evaluation through neutral third parties was conducted to select roles including leader, active or passive follower that the participants played in a triad assembly task. From the result of the correlation between behavioral data and third party evaluation, the interactive roles could have been characterized the amount of speech, i.e., potential leader talked more than potential followers. It was also suggested that the amount of gaze to other participants and the distance from them were useful cues for distinguishing active follower from passive one.

# Do we prefer simple realities or simple descriptions?

**Colleen Szurkowski**

University of Richmond

**David Landy**

University of Richmond

**Abstract:** Explanations play an important role in our mental lives. In most cases, however, explanations are not deducible outright; multiple explanations exist for any circumstance. Simplicity strongly biases preference. We distinguish between two cases: a preference for a simple underlying reality and a preference for a reality that can be simply described

We created a fictional disease scenario with three symptoms; participants rated possible diagnoses. One diagnosis was complex (3 viruses), but had a simple term; the other diagnosis involved 2 viruses. Participants generally favored the simple world over the more complex. Additionally, participants preferred whichever explanation was currently described using fewer terms. About half of participants opted for the simpler label when available, but the simpler explanation when unavailable. It seems that people take into account both the simplicity of the world model postulated by a theory and also the simplicity with which a theory is expressed, when deciding among possible options.

# **Developing and Testing "Visualizing Connection Note," a Constraint-Free Two-Dimensional Concept-Mapping Tool for Ideation**

**Yuisho Takafuji**

Chukyo University, Toyota, Aichi Pref, Japan

**Hajime Shirouzu**

Chukyo University

**Abstract:** Writing a research paper imposes a heavy cognitive load wherein one gathers ideas, develops relations among them, and decides their order. This complex, time-consuming process can be facilitated by collecting daily ideas and laying them out freely on a two dimensional map. We thus developed Visualizing Connection Note: ViCoNote, which has cloud application Evernote on its left side and a two-dimensional space on its right side. The user can easily draw various documents like texts, photos, and voice memos from Evernote to the space, and try to group, superimpose, juxtapose, and connect them. One participant used ViCoNote for two months as a pilot study, and found that it facilitated recording contextual information for brainstorming as well as condensing the information for concept mapping. We are now testing its effect for undergraduates writing their graduation theses.

# **Cognitive process of the children with reading difficulties: Analysis of the reading patterns with customizable digital reading software.**

**Maiko Takahashi**

Tokyo Woman's Christian University

**Mamoru Iwabuchi**

The University of Tokyo

**Kenryu Nakamura**

The University of Tokyo

**Abstract:** Children with reading difficulties, such as children with dyslexia, struggle with standard printed materials in regular classrooms. In this study, a reading support system with a text-to-speech function, Touch & Read, was developed to examine changes in textbook information comprehension among children. Using this system, readers can magnify text, or tap part of the text to listen to the words read aloud, and adjust the speed of such auditory feedback. The system can log the way that the reader uses it to be analyzed to report on points of difficult for a reader, as well as help estimate his or her reading process afterward. We provided the Touch & Read system to 175 students from the first to sixth grade in the regular class and asked them to use it in the lesson for reading comprehension. Analysis of our data shows improvements in the reading rate and accuracy of the children with reading difficulties and a consequent rise in reading scores. Through an analysis of the logs of the reading behavior, the differences of the reading process between the children with and without reading difficulties are discussed here.

# Infant biases in lexical acquisition induced by loosely symmetric reasoning

**Tatsuji Takahashi**

Tokyo Denki University

**Takumi Kamiya**

Tokyo Denki University

**Takahiro Shimizu**

Tokyo Denki University

**Shuji Shinohara**

Advanced Algorithms & Systems

**Abstract:** Four biases (or constraints) are known to guide word learning by infants: whole object bias, noun-category bias, mutual exclusivity, and shape similarity. They can be understood in relation to manifesting and invalidating the logical types between an object and the class or a token and the type. Hence we can suppose the biases have close connection to self-reference and our flexibility in thinking. Because the biases basically contradict each other, there must be an adjusting mechanism. We propose the loosely symmetric (LS) model as the plausible mechanism. LS, a heuristics describing human symmetric cognitive biases in the form of conditional probability, is shown to be effective in an ample amount of areas including causal induction, learning (reinforcement, supervised and unsupervised), game-theoretical situations and digital game AI. Infant agent inferring what to learn with LS shows not only efficient word learning but also appropriate use of the acquired knowledge for communication. The agent also shows appropriate adjusting of which bias prevails.

# Color Affects Face Perception in Schematic Faces

**Fumiyo Takahashi**

Hokkaido University, Sapporo, Hokkaido, JAPAN

**Yasuhiro Kawabata**

Hokkaido University, Sapporo, Hokkaido, JAPAN

**Abstract:** Previous research has revealed color effects in scene recognition and in object recognition by diagnostic tasks but only for particular objects with typical colors, whereas Changizi (2006) showed development of trichromatism in primates in terms of the evolution by computational models. Accordingly, it suggests the importance of face color as a social signal. In our previous study (2009), we found the tendency to typical colors for each emotion: red for anger, bluish colors for sadness, and yellow, orange and pink for joy. In this study, we investigate the color effects on cognition of emotional facial expression in colored schematic faces, which can represent prototypes of emotional facial expression and control the degree of change for each part; eyes and mouth. As a result, consistent colors for each emotional expression facilitated the task performance.

# Neural substrates of grammatical information retrieval during sentence comprehension

**Kei Takahashi**

Tohoku University

**Satoru Yokoyama**

Tohoku University

**Toshimune Kambara**

Tohoku University

**Ryuta Kawashima**

Tohoku University

**Abstract:** To comprehend a sentence, retrieval processes of both grammatical and lexical-semantic information from memory are required. However, previous studies had mainly focused on the maintenance process. The current fMRI study investigated the existence of information retrieval process on grammatical and lexical-semantic processing by manipulating retrieval load but by controlling maintenance load.

Two tasks have prepared; in the grammatical task participants read ungrammatical Japanese coordination construction sentences and judged in which conjunct incongruent item had appeared, and in the lexical task, the participants remembered six Japanese words and judged when the lastly displayed word appeared.

The result showed significant brain activity in the superior part and inferior part of left middle frontal gyrus in the grammatical task and in the lexical task, respectively ( $p < .001$ , uncorrected). This indicates the existence of retrieval system independently from maintenance process. In addition, grammatical information retrieval is processed distinctly from lexical-semantic information retrieval.

# **Soccer as Social Interaction between Observable Bodies**

**Katsuya Takanashi**

Japan Science and Technology Agency / Kyoto University

**Kazuki Sekine**

Japan Society for Promotion Science / University of Birmingham

**Abstract:** What is the most essential in soccer is that a player's orientation as to how s/he is about to play is expressed through bodily movements and becomes observable for other players in the process of game. And, this is not only true for soccer, but also for social interaction in general such as conversation. Therefore, it is indispensable for cognitive science of social interaction to build a methodology for grasping what a participant in interaction observes in other participants' behaviors in the on-going process of interaction as a starting point for modeling cognitive competence behind such behaviors. This presentation introduces an analytic framework for soccer in which soccer is conceived as a kind of social interaction and bodily movements in it are analyzed with reference to several analytic concepts developed in conversation analysis and gesture studies which can describe details of sequential organization of social interaction.

# **Tactile sensation and onomatopoeia in Japanese**

**Yufuko Takashima**

Dokkyo University, Soka, Saitama, Japan

**Abstract:** This paper explores words of tactile perception in Japanese investigated by using an elicitation task. Japanese language contains a lot of onomatopoeic words and has been focused on its expressiveness. On the other hand, their accuracy in haptic domain has not been often discussed. To examine the role of onomatopoeic words in tactile expression, I have used a task developed by MPI language and perception project (Majid and Levinson 2007) using a texture booklet contains ten different textures. The investigation has been held in a small village among mountains. The equality of their way of life is helpful to avoid over-generalization. Consequently, the number of texture onomatopoeic words is not enough to express tactile sensation accurately: one forth of the token contains onomatopoeic words in contrast to half of expression to try to guess the source in detail. Some onomatopoeic words are used to express more than one stimulus.

# **A remotely operated robot as a research tool to study the effects of different roles for successful collaborative learning**

**Nakayama Takayaro**

**Abstract:** In collaborative learning situations, remotely operated robots can be used to deliver the same information to different groups, so that we can explore the roles of partners in collaboration. Using this technique, we have tested 25 collaborative learning cases with eighty 5th and 6th graders on science topics. Even though the basic script for running these experimental classes was kept constant and the children learned successfully from the first case, we have found that the operators behavior changed over the course. For the first nine cases, the robots were operated as a moderator. In the following eight cases, the operators mixed this style with operations where the robot acted more like an equally capable peer. Observing some success for soliciting more active collaboration by this mode of operation, in the recent eight cases, the operators have begun to explore different possibilities of kids roles.

# **The Influence of Cognitive Functions to Acquire Nursing Skills for Patient Transfer**

**Keiko Takeda**

Nihon Fukushi University

**Yoriko Watanabe**

Seirei Christopher University

**Taeko Harada**

Nihon Fukushi University

**Abstract:** This study aims to elucidate the influence of cognitive functions on nursing skills for patient transfer. We examined the relationship between Go/No-go task (GNG) performance and self-evaluation score in the nursing care action, magnitude of low back strain during patient transfer, and decision making time for starting patient transfer. Twenty university students (mean age 190) participated in this study. The results showed that the reaction times in the GNG was correlated with the magnitude of low back strain and the decision making time. As GNG performance is related to decision making for action selection, this cognitive process appears to be associated with nursing skill. This is observed via the magnitude of low back strain and decision time for better transfer action selection. Thus, cognitive process for selecting the nursing care action may be related to the nursing skills.

# **The effect of 3D stereoscopic display on spatial cognition: a near-infrared spectroscopy study**

**Yoshiyuki Tamamiya**

University of Tokyo

**Kazuo Hiraki**

University of Tokyo

**Abstract:** 3D stereoscopic displays have become popular in our life. Some studies show that this new technology affects our ability to recognize objects. However, it is not well known how our brain is modulated by the technology. In the current study, eighteen healthy adults participated. They were asked to make blocks same as pictures shown on a monitor. The task was similar to an intelligence test. There were two sets of pictures, 2D and 3D. The stimuli were presented through the Nvidia 3D vision system. During the task, activation in parietal area, which is related to spatial cognition, were recorded by a functional near-infrared spectroscopy (NIRS). Compared to 3D pictures, 2D pictures more activated parietal area. The result indicated that the task with 2D pictures required more spatial cognition to compute depth information of the blocks from 2D pictures, which leads to activation of parietal area.

# Understanding displacement of communication by graphical communication tasks

**Kaori Tamura**

Japan Advanced Institute of Science and Technology

**Takashi Hashimoto**

Japan Advanced Institute of Science and Technology

**Abstract:** One important feature of human linguistic communication is displacement, to communicate about absent objects. However, it has not been revealed that which aspects of displacement are unique to human beings. We claim that displacement should be considered in the context of communication and distinguished from memory to this end. We designed a graphical communication task for displaced communication based on Fay et al (2003). Two participants are paired and communicate using electric drawing pads in separate rooms. In the experiment, we investigated speakers' devices on expression to make listeners understand absent objects. We compared two different kinds of tasks: one corresponds to displacement based on memory and the other displacement not based on listeners' experience. The result shows that speakers tend to use placeholders significantly more to express events that are not based on listeners' experience. Placeholders are alternative expressions that typically have the same features with absent objects.

# Effect of embodied cognition in insight problem solving

**Masahiko Tamura**

Nagoya University, Nagoya, Aichi, Japan

**Kazuhisa Miwa**

Nagoya University

**Abstract:** We confirmed that embodied cognition improves relaxation of the fixation in insight problem solving. In this study, the embodied cognition was manipulated with eye movements in an eye-tracking task. To achieve a solution, a problem solver is required to relax the fixation that guides search in an incorrect problem space, and to shift the search into a correct one. We conducted two experiments. The participants' eye movement was controlled using an eye-tracking task prior to or during insight problem solving. Experiment 1 confirmed that the tracking task performed prior to the insight task reduced the participants' fixation guiding the incorrect search. In Experiment 2, the participants who engaged in the tracking task during solving the insight task found a correct target faster just after beginning to generate crucial hypotheses that violate the incorrect fixation than those who did not. We concluded that a stimulus accompanying embodied cognition affects fixation generation and also reduces the intensity of fixation once generated in insight problem solving.

# **For female eyes only: Comparing the effects of enlarging eyes and irises on facial attractiveness**

**Azumi Tanabe-Ishibashi**

Kyoto University, Kyoto-shi, Kyoto , Japan

**Mikina Takahashi**

Kyoto University, Kyoto-shi, Kyoto , Japan

**Maya Katsuhara**

Kyoto University, Kyoto-shi, Kyoto , Japan

**Kana Kuraguchi**

Kyoto University, Kyoto-shi, Kyoto , Japan

**Hiroshi Ashida**

Kyoto University, Kyoto-shi, Kyoto , Japan

**Abstract:** Various beauty products have been developed motivated by our general concern to facial attractiveness. The eyes and irises are quite often the main target of those cosmetic attempts to increase beauty of female faces. Many women use cosmetic items to make eyes look larger, but some Japanese women use contact lenses to make irises look larger. In this research, we compared rated attractiveness of female faces with enlarged eyes and enlarged irises. We also compared those faces in terms of likability and childishness. The result showed that faces with enlarged eyes were rated more attractive, while faces with enlarged irises were perceived more likable and childish. Moreover, female participants evaluated faces with enlarged irises more attractive, though males did not. We suggest that the eye-makeup to enlarge the appearance of irises has the effect of showing the female faces more attractive only for the viewers of the same sex.

# Gender difference of social interaction behavior in child's game

**Daisuke Tanaka**

Tottori University, Tottori, Japan

**Shinako Terakawa**

**Ayumi Seki**

Tottori University, Tottori, Japan

**Hitoshi Uchiyama**

Tottori University, Tottori, Japan

**Tatsuya Koeda**

Tottori University, Tottori, Japan

**Abstract:** It is known that the Ultimatum Game is an index of human social interaction behavior with regard to inequality aversion, correction of illegitimacy and egalitarianism. Previous research found that preference for fairness tends to occur with Theory of Mind. In general, children enhance their sociability through playing with peers. However, taking into account gender difference of playing style preference, it is possible to predict that social abilities differ by gender. In this research to find a gender difference of social behavior in playing with peers, new game based on the Ultimatum Game was constructed. Participants were 9 or 10 years old and played with 3 other same gender peers (one is a friend and two are foes) according to some rules. As a result, male tends to value his friend in comparison with female. Predictable gender difference of social abilities caused by observed behavioral traits was discussed.

# **Assignment of accent patterns to nonword items in a rapid reading task by Japanese speakers of the Kansai dialect**

**Yuki Tanida**

Department of Cognitive Psychology in Education, Kyoto university, Yoshida Hon-machi, Sakyo-ku,  
Kyoto, Japan

**Yoko Higuchi**

Graduate School of Human and Environmental Studies, Kyoto University

**Yuri Yano**

Kyoto, Japan

**Satoru Saito**

Department of Cognitive Psychology in Education, Kyoto university, Yoshida Hon-machi, Sakyo-ku,  
Kyoto, Japan

**Abstract:** Previous studies have reported the strong influence of phonotactic knowledge on a variety of language tasks. For example, nonwords composed of phoneme combinations that occur frequently in a particular language are recalled accurately in a short-term memory task. In this study, we investigated the role of another type of phonological knowledge, prosodic knowledge, which has thus far been neglected. For this purpose, an accent-pattern assignment task with tri-mora nonwords was performed by Japanese speakers of the Kansai dialect under the assumption that the phonological system might assign the typical accent pattern, which reflects accumulated knowledge about accent patterns that occur in the language environment, to non-lexical items. However, the proportion of accent patterns produced did not reflect the frequency of each accent pattern in the Kansai dialect; instead, it reflected the proportion in the Standard Japanese language, to which all Japanese speakers have presumably been exposed by the broadcast media.

# Experience-based modulation of eye-movement behaviour in dynamic and uncertain visual environments

**Shuichiro Taya**

Taisho University

**David Windridge**

University of Surrey

**Magda Osman**

Queen Mary, University of London

**Abstract:** We examined the influence of experience in tennis on eye-movement behaviour. Participants experience with the sport was recorded, along with the number, size, and accuracy of saccadic eye-movements made around 'ball events' (i.e. hits and bounces) while watching the clips of tennis match. Overall, observers with richer experience about tennis relocated their eyes quicker and closer to the upcoming event location as compared with observers with relatively poor-experience of the sport. Moreover, even though repeated exposure to the same clips increased the efficiency of eye-movements in non-experienced observers, the main differences (e.g., saccadic amplitudes) between the two observer groups was preserved. Importantly, the influence of experience was predominantly found in ball events with higher uncertainty (bounces). These results suggest that our gaze control system utilizes knowledge accumulated through past experience to anticipate upcoming events, and this helps especially when the visual event that occurs is relatively unpredictable.

# **Constructing Social Attitudes through Persuasive Writing Training: A Cognitive Approach in Undergraduate Education of Engineering Ethics**

**Emiko Tayanagi**

Future University Hakodate

**Abstract:** This study aims to seek a new approach of educational method to enable students to cultivate ethical mind as professional engineers through strategically designed course program including persuasive essay writing. On the assumption that the social psychology theories of role-taking and attitude change derive effective basis to practice such education programs, the study develops a theoretical framework for education, a syllabus of the class and a series of short essay questions to exercise cognitive abilities concerned with ethical practices. Findings from qualitative data analysis of descriptive texts by students show that this framework succeeds in providing effective training opportunities, in which students try to learn how to construct social attitudes for ethical decision making within difficult and complex situation overcoming conflict between opposing factors such as individual and organizational value. In conclusion theoretical and practical implications of the study combining modern ethics and cognitive science would be discussed.

# **The nature of the training effects of mental rotation: the limit for transfer to novel orientation**

**Haruna Terada**

University of Tsukuba

**Hiromi Morita**

University of Tsukuba

**Abstract:** We investigated the training effects of mental rotation of two-dimensional figures. 35 participants practiced rotating the upright image into the orientation between 0 to 180 with a set of 4 figures. Then they were tested on the mental rotation into the new orientation between 0 to 180 with the same set of figures (new orientation condition), on the rotation of the upside-down image into the orientation between 180 to 360 with the old figures (novel orientation condition), and on the rotation with the different set of figures (novel figure condition). There was no difference in rotating rate between the novel orientation condition and the novel figure condition. The rotating rate for these conditions was significantly lower than that for the new orientation condition. The results suggest that the training effects do not transfer beyond the path through which participants rotated images in the practice.

# **Multi-platform Experiment to Discuss Behavioral Consistency across Laboratory and Real Situational Studies**

Nagoya University

**Kazuya Takeda**  
Nagoya University

**Abstract:** We constructed an innovative experimental platform to discuss behavioral consistency in driving behavior. In our experiment, the participants were required to engage a vehicle handling task using three different systems: the real (an electric vehicle), virtual (a driving simulator) and laboratory (a computer monitor and a game pad controller) systems. The results are summarized as follows. 1) In the real system, the behavioral consistencies within participants were different among three fundamental behaviors (brake, accelerator, and steering). Whereas the consistency of the brake behavior was the lowest, the steering behavior was the highest. 2) The same pattern of consistencies in the real system was confirmed in the virtual and laboratory systems. 3) The pattern of consistencies between the real and virtual systems was similar to the real system. On the other hand, the pattern of consistencies between the real and laboratory systems was different from the real system.

# **An Exploration of Crossword Skill**

**Kejkaew Thanasuan**

Michigan Technological University

**Shane Mueller**

Michigan Technological University

**Abstract:** Past research has established how different lexical skills (word-stem completion, anagram solutions, etc.) correlate with crossword puzzle expertise. However, little is understood about the cognitive processes involved in crossword play. We hypothesize that clues are solved either through an semantic or an orthographic route, but not both simultaneously. To help us test and develop this model, we conducted an initial study examining novice crossword puzzle performance, along with a secondary word-stem completion task. We found that our participants word-stem completion correlated reliably but modestly with puzzle solution, suggesting that a number of other factors may be involved. Moreover, in our study, most responses (66%) were made with little or no orthographic constraints, suggesting that novice crossword players relied heavily on the semantic route for solving clues. The results show evidence for both routes, and provide direction for testing whether a dual-route interactive memory search is possible.

# Musical thoughts behind composer's writings

**Akifumi Tokosumi**

Tokyo Institute of Technology

**Akihiro Kawase**

National Institute for Japanese Language and Linguistics

**Abstract:** Two analysis methods were applied to the essays written by Toru Takemitsu and Pierre Boulez, two prominent contemporary composers of classical music. The purpose of the network analysis was to identify keywords and their surrounding words within the text. After applying a morphological analysis to the text, a home-brewed network creation software was employed to create a network for the extracted keywords. There are clearly several node clusters and a number of measures of centrality for the network indicate that the multi-centrality of the keyword space. The text corpus for the essays was then parsed in order to carry out a content analysis at the semantic level. The aim of the content analysis was to extract the structures within the concepts employed by the composers in talking about music. The interesting results include the findings that a) their aesthetic vocabulary is strongly associated to an abstract thinking vocabulary, and b) more ordinary emotion words tend to be associated with lower level music entities. These findings seem to substantiate the layered model of affective processes proposed in our previous report. With methodological perspectives we will argue for the following points; a) Network analysis of the words within a text can provide a better basis for text analysis. b) The modeling of affective process and text analysis may be mutually beneficial.

# **Not just for consumers: Data and theory show that context effects are fundamental to decision-making**

**Jennifer Trueblood**

Indiana University

**Scott Brown**

University of Newcastle, Australia

**Andrew Heathcote**

University of Newcastle, Australia

**Jerome Busemeyer**

Indiana University

**Abstract:** Context effects—preference changes depending on the availability of other options—have attracted a great deal of attention among consumer researchers studying high-level decision tasks. Our experiments show that all three context effects from the preferential choice literature—similarity, attraction, and compromise effects—also arise in inference tasks and simple perceptual decision-making tasks. These experiments provide evidence that the effects are not confined to high-level decision tasks where the options have hedonic values such as consumer products. A new model of multi-alternative, multi-attribute choice is also developed. This model, named the Multi-attribute Linear Ballistic Accumulator (MLBA) model, extends the Linear Ballistic Accumulator model (Brown & Heathcote, 2008) and postulates that context effects arise from a combination of cognitive components including attention, a contrast mechanism, and sensitivity to indifference/dominance. The MLBA model has an analytical solution making it computationally easier to fit to experimental data than previously proposed stochastic models.

# **A collinear distractor impairs local element search regardless of its probability occurrence**

**Chiahuei Tseng**

Department of Psychology, The University of Hong Kong, Hong Kong, Hong Kong

**Li Jingling**

Graduate Institute of Neural and Cognitive Sciences, China Medical University, Taichung, Taiwan

**William Oh**

Department of Psychology, The University of Hong Kong, Hong Kong, Hong Kong

**Abstract:** Salient distractors draw our attention spontaneously even when they do not facilitate our target search. When that occurs, targets close to or overlapping with them are detected and discriminated faster. However, an opposite impairment effect is observed when the salient distractor is a column of continuous linear bars (Jingling and Tseng, 2012). One possible explanation is that observers optimize their search strategy by directing their attention away from collinear distractors but toward the area where targets are six times more likely to appear. We tested this hypothesis by arranging targets to overlap with collinear distractor columns for 60% of the trials. The same search impairment on targets overlapping with or near the collinear distractor persists, which is against the probability hypothesis. Our result suggests that the origin of this effect is at a sensory processing stage not dependent upon information to its probability occurrence.

# Can Incubation be efficient in Reviewing?

Mio Tsubakimoto

Future University Hakodate, Hakodate, Hokkaido, Japan

**Abstract:** By examining eye movements, we reveal an effect of incubation in the reviewing process of creative problem solving. Although previous research on reading comprehension considers eye movements, the reviewing process, an important stage in writing, has not been focused on. We constructed themes with different familiarities and monitored eye movements during the reviewing process on a computer screen to record saccade, fixation, and the degree of attention paid to blank spaces. While recording the reviewing, we focused on distinguished macrostructure changes to compare the quality of texts after incubation-facilitated reviewing. Additionally, we conducted a questionnaire survey on metacognition and a semi-structured interview regarding cognitive strategy in reviewing. We examined the correlations between theme familiarities, metacognition, the quality of reviewed text, and eye movements. We propose an instructional method in writing education to reveal the correlations between the reviewing aspect of complex problem solving and incubation, a semantic cognitive process.

# **Constraint discovery hint versus constraint relaxation hint in solving insight problems**

**Syoichi Tsujii**

Chyukyo University

**Syoji Hamaguchi**

Chyukyo University

**Syota Chimura**

Chyukyo University

**Hajime Shirouzu**

Chukyo University

**Abstract:** Initial failures in solving insight problems commonly cause the solver relax his problem constraints. However, such initial trials also produce usable constraints that can facilitate further solutions.

We used a tangram puzzle (constructing a T shape from four pieces) to prepare three conditions: a constraint discovery condition wherein our confederate (acting as a member of paired participants) regularly provided two combined pieces as a hint, a constraint relaxation condition wherein the confederate regularly violated the participants constraints on how to place pieces, and a control (natural collaboration) condition. Twenty four participants were divided to one of three conditions.

We found no significant difference in the number or average time of successful solutions among the conditions. However, the constraint discovery condition outperformed the other conditions in correctly recalling the solution, indicating that, when people discover usable constraints, they retain them as basic knowledge pieces.

# Heart rate synchronization in collective creative construction tasks

**Kristian Tyn**

Aarhus University

**Riccardo Fusaroli**

Aarhus University

**Abstract:** What does it mean to cooperate? In this paper we explore the effects of cooperation on heart rate. We argue that in cooperative contexts participants synchronize their heart rhythms according to two factors: the affordances of the task at hand and the gradual consolidation of collaborative practices. We instructed 6 groups of participants to construct LEGO models of six abstract notions, both individually and in groups. We employed recurrence analysis techniques to quantify the mutual adaptability of heart rates among the participants in the different tasks. During individual tasks individual heart rates synchronized both within and between groups (but not with controls), plausibly due to the affordances of the task at hand. Additionally, during collective, but not individual tasks, within group synchronization grew over time. We finally discuss how these measures of synchronization relate to the participants engagement in the tasks at hand.

# **A Longitudinal Study on the Development of Taiwanese Childrens Use of Causal and Anaphoric Cue**

**Yuhtsuen Tzeng**

National Chung Cheng University

**Chiung-hsien Tsai**

Chung Hwa University of Medical Technology

**Abstract:** Making causal connections and anaphoric inference referring expressions is important in forming a coherent discourse representation. Causal inference is central to the representation of reading comprehension. Zero pronoun sentences are grammatical in Mandarin Chinese. Therefore, this longitudinal study focused on the development of inferring causal and anaphoric coherence among elementary school children in Taiwan.

In this two-year study, we reported data from 338 children in three age groups: 104 grade second, 123 grade third and 111 grade forth children in the first year. For each subject, 36 experimental short texts and 18 fillers in randomized order were implemented in Experiment Builder. We manipulated causality (high or low) and anaphoric resolutions (overt or zero pronoun) in texts.

The patterns in this study indicated the importance of causality for the on-line inferences. There were steady developments of causal and anaphoric inference in three age groups during the study periods.

# Measuring Learners' Awareness through Persona-Conjoint Method

**Hikaru Uchida**

Tokyo Institute of Technology, Yokohama-shi, Japan

**Akiko Orita**

Keio University, Fujisawa-shi, Japan

**Masaaki Kunigami**

Tokyo Institute of Technology, Yokohama-shi, Japan

**Takao Terano**

Tokyo Institute of Technology, Yokohama-shi, Japan

**Atsushi Yoshikawa**

Tokyo Institute of Technology, Yokohama-shi, Japan

**Abstract:** This paper proposes a novel method: "Persona-Conjoint Method"(PCM), which intends to measure the effect of learning of complex situation in a business process. In practice, such as Case Learning, learners must understand how to act at a specified complex situation, such as marketing negotiations. The method is characterized by 1) a persona-set prepared by an appropriate orthogonal array used in conjoint analysis, and then 2) the measurements for changes of evaluation viewpoints of learners. Therefore, the proposed method is able to quantitatively detect and evaluate learners' awareness about the situations difficult to detect so far. From the learners' experiments, the paper describes experimental results using Manga textbook with narrative approach. The method has revealed a set of alternative personae for the particular character of the narrative material.

# **Inhibitory control in event-based prospective memory task: An examination using the retrieval-practice paradigm**

**Kenta Utsumi**

Graduate school of education, Kyoto University

**Satoru Saito**

Graduate school of education, Kyoto University

**Abstract:** The nature of forgetting in a prospective-memory (PM) task was examined through the retrieval-practice paradigm. In two experiments, participants studied a series of category-exemplar pairs that belonged to one of eight categories (e.g., FRUIT-apple) and then engaged in retrieval practice for three members in each of four categories. At the final test phase, every participant was required to detect target items that belonged to one practiced and one unpracticed category while performing an ongoing task. Results showed the worst detection performance in response to the unpracticed items in the practiced categories versus that in response to the unpracticed items in the unpracticed categories. This retrieval-induced forgetting was smaller for the detection of focal targets, for which the processing largely overlapped with the processing of the ongoing task (Experiment 2), than for non-focal targets, for which the processing was performed independently from that of the ongoing task (Experiment 1).

# Metacognition in children is specific to domain knowledge

**Vy Vo**

University of Rochester, Rochester, NY, United States

**Rosa Li**

Duke University, Durham, NC, United States

**Nate Kornell**

Williams College, Williamstown, MA, United States

**Jessica Cantlon**

University of Rochester, Rochester, NY, United States

**Abstract:** Metacognitive skills have been shown to facilitate learning. But do they develop globally or within content domains? We used an objective measure of metacognition in two different domains to investigate this question in children. 25 subjects (5 to 8 y.o.) made numerosity judgments (which picture has more dots?) and emotion judgments (which picture looks happier?) on a touchscreen. After each judgment, they placed a metacognitive bet on their accuracy using a token economy, with immediate feedback (+3/-3 high risk, +1/-1 low risk). We measured metacognition by a phi correlation of risk choice and accuracy, finding that children were significantly metacognitive on both tasks. Higher metacognitive scores on the numerosity task, and not the emotion task, predicted mathematical intelligence. However, metacognitive scores did not predict other measures of ability, such as general IQ. Our study provides evidence that metacognition develops in tandem with domain-specific knowledge, rather than globally.

# **A study of cognitive style, visual attention distributions and achievement of Web-based multimedia recipes learning**

**Ching-Yeh Wang**

Graduate Institute of Digital Learning and Education, National Taiwan University of Science and Technology

**Meng-Jung Tsai**

Graduate Institute of Digital Learning and Education, National Taiwan University of Science and Technology

**Abstract:** This study aims to explore, based on eye-tracking data, the effect of cognitive style on attention distributions and learning achievement in web-based multimedia recipe learning. The study uses a one way (verbal style V.S. visual style) quasi-experimental design. Subjects are 29 students of hospitality. The treatments of the study multimedia recipes are including static and dynamic representation. Students prior knowledge and learning achievement are assessed via a survey. Result of this study reveals that students cognitive styles have an intimate relationship with their visual attention distributions in reading web-based recipes. And gender could play an important role in this learning context. In addition, it shows that it is effective to improve students immediate learning achievement and retention of learning when the procedural knowledge of recipes is represented by web-based multimedia. Specifically, the static multimedia materials improve students immediate learning achievement while the dynamic multimedia materials improve their retention of learning.

# **Does self extend to video game avatars? An ERP study**

**Veronica Weser**

Vassar College

**Ken Livingston**

Vassar College

**Abstract:** The extended mind hypothesis suggests that the boundaries of self are extended to that which can be controlled directly. Avatars in video games fit this description but are not embodied in the way generally assumed by EM theory, thus providing an opportunity to test the generality of the hypothesis in a domain that actually invites mental extension of self beyond body boundaries. We compare ERP responses to images of self, own avatar, other avatar, own possessions (real & virtual), and other possessions (real and virtual) after participants have spent three weeks playing both Second Life (avatar designed and directly controlled by player) and Sims 3 (avatar generally configured but not directly controlled). We test the hypotheses that N170 waveforms are distinct for images of the self and of others, while N250 is different for personal possessions and unfamiliar objects and P300 functions as an index of attention to self-relevant stimuli.

# **Social information aids accuracy but hinders adaptation**

**Thomas Wisdom**

Center for Experimental Research in Social Sciences, Hokkaido University

**Keigo Inukai**

Department of Economics, Hokkaido University

**Wataru Toyokawa**

Department of Behavioral Science, Hokkaido University

**Kameda Tatsuya**

Center for Experimental Research in Social Sciences, Hokkaido University

**Abstract:** We introduce a simulated investment task combining a temporally varying "market" environment with a 6-armed bandit using heterogeneous payoff distributions. It includes uncertainty about the binary state of the market, as well as which of several options yields the best payoff under each hidden market state. The mean performance of grouped participants (who could view peers' choices) did not change over the course of the session, while isolated participants had lower initial performance but higher final performance than grouped participants. Further analysis showed that grouped participants benefited from relatively accurate but low-risk-biased social information, while isolated participants developed a higher tolerance for ambiguity, reducing their use of costly prediction for high-risk choices more than did grouped participants. Our results imply that social information can cushion individual performance under uncertainty, but may hinder learning and adaptation to a dynamic environment.

# Searching for something familiar or novel: ERP correlates of top-down attentional selection for specific items and categories

**Rachel Wu**

Birkbeck, University of London

**Gaia Scerif**

University of Oxford

**Richard Aslin**

University of Rochester

**Tim Smith**

Birkbeck, University of London

**Martin Eimer**

Birkbeck, University of London

**Abstract:** Visual search is often guided by top-down attentional templates that specify target-defining features. But, search can also occur at the level of object categories. We measured the N2pc component, a marker of attentional target selection, in a visual search task using familiar and novel targets. Targets were defined either categorically (e.g., any letter), or at the feature level (e.g., the letter C). An N2pc was elicited during category search, in both familiar and novel contexts, indicating that even when targets are only defined at the category level, they are selected at early sensory-perceptual stages. However, the N2pc emerged earlier and was larger during feature-based search, demonstrating the superiority of attentional guidance by feature-specific templates. Moreover, category search triggered feature-specific templates, while the inverse was not the case, suggesting that higher-order search templates automatically include lower-order templates.

# Practicing Off ice Collaborative Learning in a University Ice Hockey Team

**Masayuki Yamada**

The Center for the Promotion of Integrated Sciences, The Graduate University for Advanced Studies

**Masaki Suwa**

Faculty of Environment and Information Studies, Keio University

**Abstract:** This research is a case study of collaborative learning in a university ice hockey team. Collaborative learning were held twice a week for about two months. There were three teams of collaborative learning, each group consisting of five participants. Each group selected a theme to be discussed concerning the strategy for playing a game, analyzed videos, and made a presentation about their analysis. They had been writing memos of meta-cognitive thoughts about ice hockey on a daily basis before the meetings. We analyzed their meta-cognitive writing before and after their practice. Moreover, we carried out game analysis in order to assess the effect of performance as a team. As a result, new descriptions, had not appeared before this study, arised in their meta-cognitive writing. And it indicate a change in their behaviors. Also, the game analysis indicates that their performance improved from before the practice.

# **Design of motion using mimetic words**

**Kaori Yamada**

Kobe University, Kobe, Hyogo, Japan

**Toshiharu Taura**

Kobe University, Kobe, Hyogo, Japan

**Yukari Nagai**

Japan Advanced Institute of Science and Technology

**Abstract:** Today, with several media of expression being available, the field of design has come to address more dynamic and impressive objects such as sound and computer graphics. In this study, we attempt to design such a creative and emotional motion that resonates with deep feelings that are difficult to verbalize using mimesis in the Japanese language and we believe that mimetic word is capable of expressing deep feelings. While onomatopoeic (sound-symbolic) words imitate actual sounds, mimetic (reality-symbolic) words, for example, shiku-shiku (sobbing) and kune-kune (wriggling), express appearance, movement, feeling, and other phenomena. We extracted mimetic words which indicate movement from other mimetic words. We showed how using mimetic words can help identify suitable motions that can be combined to create a new creative and emotional motion. This motion can be applied to such elements as animated logos and be used to create appealing advertisements.

# Stochastic dynamics hidden in Japanese martial arts

**Yuji Yamamoto**

Nagoya University

**Motoki Okumura**

**Hiroo Suzuki**

Nagoya University

**Kazutoshi Gohara**

Hokkaido University

**Abstract:** Martial arts like judo or Japanese fencing (kendo) are considered typical interpersonal competitions of human motor behavior. This kind of competition requires one to attack an opponent while simultaneously avoiding the opponent's attack. To quantify the practical behavior of interpersonal distance (IPD) between two players from the viewpoint of a dynamical system, we observed players' movements in kendo matches by a motion capturing system. The participants were twelve college athletes whose team had won in All Japan championships. The time series of the IPD from the coordination phase to the attacking phase was extracted, and 419 scenes were analyzed. A return map analysis was applied to the data using peak detections. We could describe the interpersonal competition during a kendo match in terms of state transitions, as in a Markov process. This suggests that complex human movements in interpersonal competition are self-organized by a simple principle. Martial arts like judo or Japanese fencing (kendo) are considered typical interpersonal competitions of human motor behavior. This kind of competition requires one to attack an opponent while simultaneously avoiding the opponent's attack. To quantify the practical behavior of interpersonal distance (IPD) between two players from the viewpoint of a dynamical system, we observed players' movements in kendo matches by a motion capturing system. The participants were twelve college athletes whose team had won in All Japan championships. The time series of the IPD from the coordination phase to the attacking phase was extracted, and 419 scenes were analyzed. A return map analysis was applied to the data using peak detections. We could describe the interpersonal competition during a kendo match in terms of state transitions, as in a Markov process. This suggests that complex human movements in interpersonal competition are self-organized by a simple principle.

# A Classification of Manner Adverbs in Korean: A Frame-based Approach

Myung-Jin Yang

Hankuk University of Foreign Studies

**Abstract:** There have been difficulties in providing a unified account of Korean adverbs. For example, in contrast to English, most manner adverbial expressions in Korean do not occur as adverbial complements to verbs, denying one way to characterize this type of expressions. The aim of this paper is to provide some criteria for classifying and categorizing manner adverbs in Korean based on frames. In the first part of this paper, we lay out the general syntactic position and semantic interpretation of Korean manner adverbs. In the second part, we present a systematic description and classification of manner adverbs using a formal apparatus based on the Operator and Davidsonian approaches (Schaefer, 2004). Finally, we propose appropriate frame structures for adverbs of manner, making reference to the Berkeley FrameNet (BFN), which we show are useful in identifying the frame types of manner adverbs and in sub-classifying individual lexical units (esp., verbs) in Korean test data.

# **Brain activities for different cohesion type on discourse comprehension**

**Ken Yasaka**

Tohoku University

**Satoru Yokoyama**

Tohoku University

**Kei Takahashi**

Tohoku University

**Ryuta Kawashima**

Tohoku University

**Abstract:** In order to comprehend discourse, the sentences in the discourse should be appropriately combined. What combines two sentences with each other is called cohesion. Theoretically, there are four types of cohesion conjunction, ellipsis, lexical cohesion, and reference. Previous neuroimaging studies investigated brain activities for cohesive and incohesive discourse, but no studies distinguished the types of cohesion. This study compared the brain activities of four cohesion types using fMRI. Participants were asked to read cohesive/incohesive discourses, each of which were combined with one of four types of cohesion, and to judge whether the discourse was coherent or not. There was no significant difference in brain activation among the four cohesion types, suggesting that the different cohesion types are recognized by a common brain mechanism.

# **Ad hoc creature: Lost and added in translation from description to depiction**

**Sachi Yasuda**

The University of Tokyo

**Masashi Okamoto**

Ritsumeikan University

**Eiji Aramaki**

The University of Tokyo

**Abstract:** When asked to draw a rabbit, almost all people can draw a rabbit correctly. In contrast, is it possible that using only descriptions of appearance features of a rabbit could achieve the same task?

We prepared a description of rabbit from a dictionary (230 words), and masked rabbit in it. The description contains 40 appearance features of rabbit. Then, subjects (n=41) were asked to draw a creature from the description.

As the result, the average 15 features (35%; min 2%, max 53%) have appeared in each picture. This indicates that people did not use all of the description to draw the target. Moreover, some people tend to draw undescribed features: a tail (40%), whiskers (10%) and wings (4%).

The result suggests that description-to-depiction translation might involve not only bottom-up processing from appearance features of a target, but also top-down processing from an ad hoc creature image in mind.

# **The influence of biological cues on the patterns of categorization in non-mental retarded PDD**

**Hsiang-Chun Yeh**

National Cheng Kung University

**Jon-Fan Hu**

National Cheng Kung University

**Abstract:** Categorization plays an important role in the development of abstract thinking and helps subjects to cope with complex social interaction. However, in literature, there are a lot different claims about the categorization in pervasive developmental disorder (PDD). In present study, we aim to clarify whether, specifically, biological cues would influence non-mental retarded PDD in categorization. We used the short form of Wisconsin Card Sorting Test (WCST) pertaining with and without biological information to evaluate categorization ability in non-mental retarded PDD and typical developmental subjects. It was found that non-mental retarded PDD have more intact responses for physical categories than biological categories. These results allow us to highlight the patterns of deficits in prototype categorization, conceptualizing social function and accompanied specific category learning of PDD.

Keywords: categorization, biological cues, pervasive developmental disorder (PDD), WCST

# Determining people's expectations about the form of causal relationships

**Saiwing Yeung**

University of California, Berkeley

**Chris Lucas**

Carnegie Mellon University

**Tom Griffiths**

University of California, Berkeley

**Abstract:** How people make inferences about causal systems with multiple potentially interactive causes is an important but complicated question. We conducted an experiment using a blinket detector task with an iterated-learning design to study people's prior beliefs about functional form. Participants observed stimuli and generated predictions based on their observations. Some of these predictions were then observed by the next participants, ultimately converging on answers that reflect only people's prior beliefs. Our results suggest that people make judgments by balancing a preference for simple causal systems against one for adequately explaining the available data. To explain these results, we propose a novel computational model that features a grammar-based prior, expressing causal relationships as compositions of three atomic forms. This model outperformed one that is based on the noisy-OR and captured people's expectations about such causal systems, suggesting the importance of logical operations — disjunction, conjunction, and negation — in characterizing people's causal knowledge.

# **The role of linguistic inputs on bilingual language development**

**Michael C. W. Yip**

The Hong Kong Institute of Education

**Abstract:** The variable of linguistic inputs plays a critical role in language acquisition and language development. The present study examined this research question by conducting a detailed day-by-day language analysis on all the linguistic inputs perceived by a group of Chinese-English bilingual infants for three months. Through language recording and analysis, some estimates are obtained of the linguistic properties of the words as well as the language structures perceived by the infants. The preliminary findings provide a solid and realistic picture of the different categories and properties of the linguistic inputs spoken to and around the infants. Important implications from the present set of data for the study of bilingual language development will be discussed.

# Nothing-absence difference in causal induction and the pARIs rule

**Junki Yokokawa**

Tokyo Denki University

**Tatsuji Takahashi**

Tokyo Denki University

**Abstract:** In a novel environment, we establish causal relationship by inductive inference from statistical data. Although recent studies on causal induction focus on causal structure rather than intensity, how we induce the intensity from co-occurrence of an effect and a candidate cause remains important as far as the environment is of novelty. We propose a heuristic for causal induction, the proportion of assumed-to-be rare instances (pARIs), and test its rationale and the descriptive validity. The pARIs rule is based on the rarity assumption that is quite often used in rational analysis approach (e.g., Oaksford & Chater, 1994) intimately associated with the frame problem. As for the descriptive power, we show that pARIs best fits the experimental results with the highest correlation and the minimum error. In regard to the rationale, we tested how we assume the rarity of the events we focus on. We confirmed that we rigorously distinguish between rare and non-rare events, in spite of their identical status as data.

# Proficiency in foreign language reading: the relationship between proficiency test score and reading times

Satoru Yokoyama

Tohoku University

**Abstract:** The more proficient learners are at a foreign language, the faster they can process that foreign language; hence, processing speed is one of most important indices of foreign language proficiency. Yet there are few studies which examine the relationship between proficiency levels and processing speeds. In the present study, I looked at how the English proficiency test scores of 35 Japanese learners related to the speed at which the learners processed written English sentences. The results showed a statistically robust correlation between listening test scores and the processing speed of sentences which subjects read ( $p < 0.05$ ), but not between reading test scores and general processing speed ( $p = 0.5$ ). These results indicate that the reading speed of sentences in a foreign language is strongly related to listening proficiency, which proceeds to suggests that reading speed in a foreign language can be used as one index of listening proficiency.

# **Toward a history-sensitive description of syntactic development**

**Masato Yoshikawa**

Keio University

**Abstract:** Under the empiricist theory of language acquisition known as Usage-based Model it is assumed that the process of acquisition is gradual, from concrete to abstract; infants representation of grammatical knowledge is considered to be "acquired" in bottom-up fashion. This view is compatible with recent, that is, non-traditional, theories of machine learning such as connectionist models, and therefore it can be said to have a plausibility at least from a computational point of view. At the same time, however, descriptive plausibility should be achieved. In this study, an innovative method called History-Sensitive Description (HSD) is presented in order to describe the development in the usage-based fashion. This method utilizes the history of the utterances by one infant to describe the current knowledge state of the infant. HSD gives us a set of representation at any moment of development if a longitudinal data is given.

# **Pictogram Network to Support English Composition Instructors**

**Sayuri Yoshizawa-Watanabe**

Hoshi University

**Masaaki Kunigami**

Tokyo Institute of Technology

**Satoshi Takahashi**

Tokyo Institute of Technology

**Atsushi Yoshikawa**

The Japan Institute for Educational Measurement, Inc.

**Takao Terano**

Tokyo Institute of Technology

**Abstract:** Pictogram Network is a network representation with drawings, which illustrates information or knowledge that is difficult to transfer via usual conversation. Writing an essay with a complex context requires a high level of language skills, especially in foreign languages. This paper describes the basic principles of Pictogram Network and proposes a novel support method for peer review activities for English as a foreign language composition education. When applying the method to the composition learning, the learners are required to select pictograms from the provided list and link them in order to convey the main purport of their essays. The results will not be affected by inessential factors such as spelling errors and trifling grammatical or syntax errors. Therefore, ambiguities of the context about the composition topics will become clearer than in the conventional method. The proposed method also helps to indicate illogicality of the context in writings, and will be useful even in multi-lingual environment.

# Preschoolers Use Timing of Causal Actions as a Cue for Categorization

**Yue Yu**

Cornell University

**Tamar Kushnir**

Cornell University

**Abstract:** This study examined how childrens categorization is influenced by adults social cues, particularly whether adults performed causal actions before or after a sorting demonstration. In Experiment 1, preschoolers saw the experimenter sort toys with different surface features (colors) and causal properties (sound produced when shaken) into two boxes. When the experimenter shook the toy to produce a sound before sorting (shake-first condition), children were more likely to later categorize the toys based on sound. However, when the experimenter performed the same shaking action after sorting (shake-last condition), children were more likely to sort the toys by color. Experiment 2 further demonstrated that children in the shake-first condition continued to categorize a new set of toys by sound, and they did so even in free play. These results suggest that children use adults cues in particular, the timing of adults causal actions to determine whether causal properties are relevant for categorization.

# **The Rhetoric of Defamiliarization for Narrative Generation using the Constraints in a Conceptual Dictionary**

**Yike Zhang**

Graduate School of Software and Information Science, Iwate Prefectural University

**Junpei Ono**

Graduate School of Software and Information Science, Iwate Prefectural University

**Takashi Ogata**

Faculty of Software and Information Science, Iwate Prefectural University

**Abstract:** Through an analysis of advertising rhetoric, we have acquired an idea that much of the interestingness in advertising works are grounded on the rhetoric of defamiliarization for the components. The defamiliarization is originally a literary idea which was proposed by Shklovskii and Brecht and means a literary technique for changing a familiar object into unfamiliar one to reinforce the impression. For example, the impression of a familiar product is reinforced by the application of defamiliarization techniques to the objects and agents. This idea will be able to generalize to narratives other than the advertising narrative. In this paper, we summarize the techniques for operating the level of single event by the defamiliarization rhetoric combined with a conceptual dictionary for noun concepts and verb concepts. The techniques have twelve types including three types of regular rhetoric and other irregular rhetoric. The latter transforms the elements like action, actor, product (object) and location in an event into strange or preposterous things. In our integrated narrative generation system in which this module is incorporated, this function is associated with a mechanism to be able to flexibly adjust a variety of generation from realistic narratives to fantastical narratives.
